# Vol 252 No 5478 November 1 1974 Macmillan Journals Limited

### SEARLE DIAGNOSTIC

### **Mouse Theta Antisera**

C3H anti AKR, AKR anti C3H CBA anti AKR, AKR anti CBA \*

### **Cultured Human** Lymphocytes

Available viable or frozen

### **Virus Products**

Encephalomyocarditis virus and Sendai Fusion virus available

### **Rabbit Globin Messenger RNA**

### Ribonuclease Inhibitor

Derived from rat liver

### RNA Markers

for gel and gradient analyses 4S-37S range, labelled & unlabelled

### **HL-A Antisera**

Several types now available

### H-2 Antisera\*

Derived from cross immunisations of mouse a, b, d and k genotypes

### Oligo (dT) Cellulose

### **Lithium Dodecyl** Sulphate\*

SDS derived detergent soluble at low temperatures

### Rat Alloantisera\*

Pvg anti Wag Wag anti Pvg Wag anti Agus Agus anti Wag

### Anti-Lymphocyte\* Serum

Mouse and Human

\* New addition to the range Full information is available on request

Apomorphine and morphine stimulate prostaglandin biosynthesis—H. O. J. Collier, W. J. McDonald-Gibson and S. A. Saeed

Inhibition of alweoprotein and shoolinid surethesis in beautiful for the control of the control o

Inhibition of glycoprotein and glycolipid synthesis in hamster embryo cells by cytosine arabinoside and hydroxyurea—A. O. Hawtry, T. Scott-Burden and G. Robertson

Assignment of the human gene for galactokinase to chromosome 17— T. Orkwiszewski, T. A. Tedesco and C. M. Croce

### Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to earlie 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

- (i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.
- (ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the World List of Scientific Periodicals, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-bepublished volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of Nature. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in Nature (246, 238; 1973).

Opossum Hb chain sequence and neutral mutation theory—P. Stenzel  Preservation of antigenic properties of macromolecules over 70 Myr—E. W. De Jong, P. Westbroek, J. F. Westbroek and J. W. ### A hundred years ago

Some of the Paris newspapers announced that M. Wurtz, Dean of the Faculty of Medicine at Paris, would be obliged to resign; the Figuro went so far as to give the name of the intended successor of the celebrated Professor of Chemistry—a M. Depaul. The rumour happily has proved false, and was maliciously spread because a clerk employed in the office of the Faculty had been dismissed for misdemeanour. There is, however, to be a demonstration among the students in honour of M. Wurtz, who is a great favourite with them.

# Britain reviews its defence

THE results of the British defence review initiated after the February election will soon be published and now, with Labour safely returned, they are likely to be received favourably by the government. Already political vultures are surrounding the Ministry of Defence and pointing to what they could achieve if handed a tiny fraction of the money allotted for defence; the impressive list runs from better hospitals to more performances of operas. The snag is that it is most unlikely that defence spending will be trimmed by any significant amount and certainly not by the £1,000 million, or 30%, that the left wing has been demanding.

The early talk, and indeed that enshrined in Labour's recent election manifesto, was of bringing Britain's defence expenditure into line with that of its western European partners. Later in the election campaign, perhaps when the contents of the review had been made known to Labour politicians, the talk was more mutedly of not expanding expenditure and of carefully reconsidering overseas commitments when they come up for review. An uninformed guess, then, is that the review, far from revealing large areas of fat to be trimmed off, will simply say that Britain must be more modest in future. For the statistics on European comparisons show clearly that to talk of bringing expenditure into line with that of, say, France and Germany depends very much on what criterion one uses for being 'in line', and by one criterion, at least, Britain is irreproachably in step. The accompanying table provides some relevant figures on military spending in Western Europe.

Since 1950, military spending by European countries has grown relatively slowly, once inflation has been accounted for. Indeed in the years 1949-68 Britain's military expenditure grew on average by only 2.2% per year. France, with its nuclear development in the 1950s, showed a higher rate of 5% per year and West Germany,

re-arming, grew by 6% per year. But all three countries had, by the late 1960s, stabilised their expenditure, and defence, in real terms, was hardly growing at all. As the table shows, growth subsequently re-established itself; only France has managed to keep things in check. Not too much, however, should be made of this recent growth, which may well reflect the difficulty of preventing military costs from rising more rapidly than other costs in inflationary times rather than any deliberately expansive policy.

What is evident from the table is the serious weakness that a depressed gross national product (GNP) imposes on a country with global and nuclear pretensions. In other ways Britain's expenditure looks quite lean and there is no conscription, by contrast with France and Germany, not only to put up the expense of the forces but to pull young men out of productive (and taxpaying) occupations. It is the percentage-of-GNP indicator that makes Britain seem so far out of line; there are few other countries in the world which spend as much of their GNP on defence.

The question is thus not one of how to save a few million pounds here and there with small scale economies. It is much more fundamentally, should Britain go on spending defence money at the same per capita rate as her near neighbours, thereby providing highly sophisticated armaments for her forces, or should she recognise her economic limitations and aim to bring the figure of 4.9% down to nearer, say 3.5%?

Presumably major surgery, such as the elimination of Britain's nuclear capacity, is the only way that such a saving could be achieved in the next ten years, and this is not an option that is likely to have been considered seriously. This is a shame; the rationale for possessing nuclear weapons is not so strong that it could not profit by occasional exposure and criticism if only to ensure that a new generation, to whom CND is only an historical episode, is appraised of the disadvantages, as well as the supposed advantages of the possession of nuclear weapons. It would be unfortunate if these items of mass destruction came to be forgotten about by the public and thus subject to the pressures only of technological momentum and of those employed in their construction.

Be warned that all comparisons of military expenditure suffer from variations in definitions. Thus this table should be seen as no more than general indication of comparisons. See page 102 of *The Military Balance* for more detail.

### Agriculture and sunspots

WORLD food reserves have, recently, been larger than the variability in production associated with the weather, and oscillations about the general upward trend of agricultural productivity could be ignored. It is now apparent, however, that urgent consideration has to be given to the impact of climatic changes on food production. The world's grain reserves have dwindled from the 1969 peak (19% of annual consumption) to only 7% of annual consumption, less than the variability of about 10% induced by the weather. Although many people have reported associations between the solar cycle and the weather, relatively little attention has been paid to the fact that the 11-year and the 22-year sunspot cycles could produce important modulations of agricultural productivity.

The world wheat production figures for 1949-73 can be used to show how the sunspot cycles appear to influence food production. Sunspot maxima occurred at the end of 1957 and again in 1968 and it seems significant that global wheat production in 1958 was greater than in each of the next five years, whereas that in 1968 was greater than the average of the next four years. In 1954 (a year of sunspot minimum) production was less than in any of the two preceding or the two following years. In North and Central America, for example, the crop in 1954 was smaller than any other year for which we have data; the average crop during the five previous years was 25% bigger than that of 1954.

The fact that wheat production in the Northern Hemisphere increases at around sunspot maximum can be deduced from the wheat figures for many countries. In the People's Republic of China, the annual production during 1956-58 (centred on the 1957 sunspot maximum) was 22% greater than during the period 1960-65; the total produced in 1958 has not been equalled in any year up to and including 1973. The average production in the Soviet Union during 1956-58 was, as in China, greater than during 1960-65; in 1958 the crop was 54% bigger than in 1963. The average wheat production in Canada during 1967-69 (centred on the 1968 sunspot maximum) was 27% greater than that during the four subsequent years, 1970-73; production in both 1968 and 1969 was higher than in any of the four years 1970-73.

Over much of the Northern Hemisphere, therefore, wheat production appears to be significantly enhanced near sunspot maximum and reduced at sunspot minimum. In parts of the

Southern Hemisphere, however, the opposite is observed. In Argentina, for example, the three years when most wheat was produced were 1954, 1964 (the two sunspot minimum years) and 1963; the average crop for these three years was 50% greater than for the nine years 1965-73. The African wheat crop in 1954 was bigger than in any of the next eight years; it was thus, as in Argentina, bigger than in any year until 1963. In Australia the 1957 (sunspot maximum) crop was smaller than

Researchers at the Appleton Laboratory, in England, say that the present low level of world food reserves may be associated with the decline in solar activity during the approach to the 1974-75 sunspot minimum. Presumably because of their effects on temperature and rainfall, the 11-year and 22-year sunspot cycles appear to influence agricultural productivity in certain parts of the world. Modulations of 10% to 50% of the wheat production in China, the United States and the Soviet Union seem to be correlated with the solar cycles, suggest J. W. King; E. Hurst, A. J. Slater, P. A. Smith and B. Tamkin. The forthcoming World Food Conference in Rome might well wish to discuss implications for global agricultural planning.

in any of the previous eight years; in these eight years an average of 83% more wheat was produced than in 1957.

The facts show that the modulation of wheat production associated with the 11-year sunspot cycle seems to be at least 10% in many parts of the word; in certain countries it may even be greater than 50%. A consequence of this modulation may be the fact that the Soviet wheat crop in 1972 was smaller than that of 1971 which was, in turn, less than that of 1970. It is well known that the 'failure' of the 1972 crop led to massive purchases of wheat from the United States and it may reasonably be suggested, in view of the reduced Soviet crops in the years following the 1957-58 solar maximum, that this failure was associated with the decline of solar activity between the 1968 sunspot maximum and the minimum due in about 1974.

Figure 1 shows that the yield per acre of two crops in Britain appeared to be negatively correlated with sun-

spot number during two complete solar cycles between 1937 and 1957. The cycles seem to have been accompanied by a 10% modulation of the yield per acre but it should be stressed that the relationship between agricultural productivity and the sunspot cycle is not always as clear as Fig. 1 would suggest; some reasons for this are discussed later.

It is not appropriate to describe here the complicated relationships that exist between the solar cycle and the weather in different parts of the world, but some examples of the association between sunspot number, temperature and rainfall are worth mentioning. Figure 2 shows how the rainfall at Fortaleza in Brazil varied during the 'double' or 22-year sunspot cycle; data are plotted for the period 1865-1925 which covered almost three double solar cycles. The rainfall followed the double sunspot cycles closely and the modulation associated with the double cycle amounted to about 35% of the average annual total. P. D. Tyson, as reported in the Johannesburg Star in April this year, observed that the rainfall in parts of South Africa exhibits a pronounced modulation (approximately 25% of average annual total) with a period of about 20 years. We have noticed that this oscillation closely resembles the double sunspot cycle and also that the shorter-period oscillation which Tyson observed in the rainfall over the most southerly part of Africa is in antiphase with the 11-year sunspot cycle.

The rainfall in parts of North America is also strongly influenced by the double sunspot cycle. W. O. Roberts<sup>1</sup> has pointed out that droughts in certain regions of the United States that are important for agricultural purposes occur in the years around every second sunspot minimum. The last drought was centred on the sunspot minimum year 1954 and we believe it is significant that the wheat crop in the United States in that year was 12% smaller than the average for the five previous years. It is also significant that in 1974, when the next drought was to be expected, lack of rain has adversely affected the maize crop in the United States. The wheat figures for 1949-73 suggest that Australian wheat production is also influenced by the double sunspot cycle.

Figure 3 shows how the July temperature in central England varied during the 130 years from 1750–1880; evidently a modulation of about 0.75° C occurred in phase with the double sunspot cycle except for a short period around 1850 when the phase of the temperature variation jumped by half an 11-year cycle. More recently, the growing

season (a measure of temperature) in Scotland has undergone a 10% fluctuation in phase with the 11-year sunspot cycle. The rainfall in England also appears, during the past 80 years at least, to have been influenced by the 11-year cycle. Data from Kew (1891-1930) and Bedford (1931-70) show that the rainfall there underwent a modulation in phase with the 11-year cycle. Averages for periods of four years around the sunspot maxima and four years around the sunspot minima (the extreme year of the solar cycle being the third of the four years in every case) show that at Kew the average rainfall at sunspot maximum (four sunspot maxima, 16 years) was 17% greater than at sunspot minimum (three sunspot minima, 12 years). At Bedford the rainfall at sunspot maximum (16 years) was 16% greater than at sunspot minimum (16 years). It does not seem unreasonable to suggest, since the 11year sunspot cycle appears to modulate both the rainfall and the temperature over Britain, that agricultural productivity may be affected by the solar cycle.

The temperature data shown in Fig. 3 provide evidence of a long-period variation which will be described elsewhere, but it should be pointed out here that the phases of the two longperiod temperature variations (78 years and 181 years) observed in parts of the Northern Hemisphere are such that the maximum temperatures associated with these variations occurred in 1934 and 1922 respectively; the period around 1930 was thus relatively warm. It is well known that the period around 1700 was relatively cold; it is referred to as the "Little Ice Age". Temperature data published by Manley<sup>2</sup> for central England can be used to show that the average length of the growing season during the decade 1691-1700 was about 220 days. Temperatures from Kew for the particularly favourable decade 1931-40 show that the average length of the growing season was approximately 280 days and it is evident (without allowing for the slight temperature difference which exists between central England and Kew) that long-term temperature trends are sufficient to cause the growing season in England to vary by about 60 days, approximately 25%. A return to the conditions which existed around 1700 would obviously result, from an agricultural point of view, in a much less favourable environment than that which has existed during the twentieth century. It is worthy of note that a downward trend (based on farmers' estimates compiled each year for six different crops, and published in The Times, September 2 this year) appears to have occurred recently in British agricultural productivity. The average estimate (with 100%

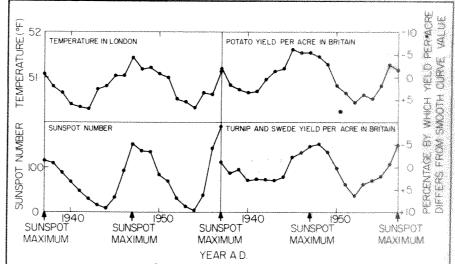

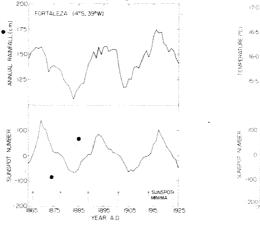

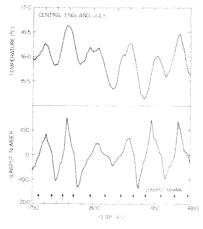

Figure 1 (above) shows variations during two complete sunspot cycles. Top left: 5-point mean of mean annual temperatures at Kew, London. Bottom left: Yearly mean sunspot numbers. Right: Percentage differences between 5-point mean of yearly agricultural yields and the trend obtained by drawing a smooth curve through the 5-point means. Figure 2 (below left): Top: 13-year mean of annual rainfall at Fortaleza, Brazil. Bottom: Yearly mean sunspot numbers, plotted with "even" 11-year cycles inverted in the usual representation of the "double" or 22-year sunspot cycle. Figure 3 (below right): Top: Smoothed mean of the central England July temperatures. Bottom: Yearly mean sunspot numbers, plotted with the even 11-year cycles inverted.

indicating 'full growth') for the years 1964-68 was 94.23%, whereas for the years 1969-74 it was only 91.86%. These figures indicate a decline of 4.6% per decade and, although evidence such as this cannot be used to establish the exact connection between agricultural productivity and long-term climatic trends, it does suggest that the gradual return to colder drier weather which has taken place recently may be having an adverse effect on agricultural output in Britain.

The physical processes through which solar radiation changes associated with the 11-year and 22-year sunspot cycles affect the weather have not yet been identified. At present there is not even a general picture, much less an explanation, of how the climatic effects associated with the solar cycles vary over the Earth. It is already known, however, that the 11-year cycle and the rainfall are positively correlated at some latitudes and negatively correlated at

others; such information could be important for agricultural planning purposes. It is also known that the phase difference between the solar cycle and the rainfall variation at particular locations undergoes sudden jumps of up to 180° but the pattern, if any, of such changes is not known.

Much more work needs to be done to establish the spatial morphology of the various climatic effects associated with the sunspot cycles. It seems reasonable, however, to expect that during the next decade man's knowledge of the effects of the 11-year and 22-year cycles on the weather may advance sufficiently for some of these to be taken into account in global agricultural planning. We thank Mr E. H. Locke and Professor P. D. Tyson for supplying data.

# international news

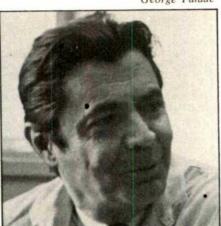

Modern cell biology can now be considered fully established as a rigorous experimental science with the award of this year's Nobel Prize for Medicine and Physiology to Albert Claude, Christian de Duve and George Palade. No other group of biologists has done more than these three laureates to advance our knowledge of the spatial organisation within the cell of diverse biochemical functions—particularly in higher organisms.

To Albert Claude, now 75, it must be particularly gratifying to see this recognition of his pioneering work begun nearly 35 years ago. It was at the Rockefeller Institute (now Rockefeller University) in 1940 that Claude, having recognised the inadequacy of light microscopy and histochemical techniques then available for correlating intracellular structures with their biochemical functions, began to apply electron microscopy to biological material. Also in the early 1940s, he devised the first successful procedure for resolving cellular organelles by the technique of differential centrifugation.

It was the combination of electron microscopy and differential centrifugation of disrupted cells that rapidly laid a foundation for cell biology as we know it. Claude recognised the importance of treating cells with utmost gentleness, both in preserving their structure and during their disruption, in order to gain further insight into the relationship between morphology and function of individual intracellular components. This was soon rewarded by the electron micrographs, taken with K. Porter and E. Fulham which revealed the ultrastructure of cultured animal cells, as well as by the first useful method for biochemically studying isolated mitochondria. The examination of isolated mitochondria in the electron microscope and the analysis of their characteristic enzyme activities in the test tube validated the biochemical studying of isolated subcelfunction in vivo, although there were many who remained sceptical of this approach. Claude soon extended the principle of differential centrifugation to derive a particulate fraction from rat liver cells which were less dense than mitochondria and which he called "microsomes". It was another decade, however, before their intracellular origin and their importance in protein synthesis and secretion, as well as in drug detoxication, were fully realised.

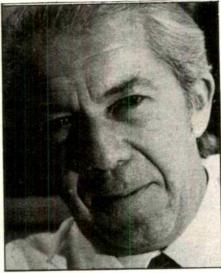

### Nobel Prize 1974

George Palade

Claude's mitochondria isolated from rat liver were heavily contaminated with other subcellular components and the procedure of differential centrifugation was improved in 1948 by his students at the Rockefeller Institute, Hogeboom, Schneider and Palade. Their procedure forms the basis of all the variants used at present in biochemical laboratories throughout the world for preparing active mitochondria and it is hard to overemphasise the impact this development has had on our present concepts of oxidative phosphorylation and biogenesis of mitochondria. Equally im-

Christian de Duve

portant is the fact that the Hogeboom-Schneider-Palade technique formed the basis for the isolation in an active form of other subcellular organelles, to be taken up by de Duve and Palade.

In 1949, Claude returned to his native Belgium to take up the directorship of the Institut Jules Bordet, an event of some importance to Christian de Duve who had then taken up the Chair of Physiological Chemistry at Louvain. De Duve's group was then struggling in an ill-equipped laboratory with the question of the effect of insulin on glycolysis in liver tissue homogenised brutally in a kitchen blender, with "typical disregard of cellular organisation", as de Duve himself expressed a few years later. But Claude's presence was immediately felt when the Louvain group (which included H. Hers and J. Berthet) adopted the swingout ultracentrifuge rotor for investigating the close association of certain groups of hydrolytic enzymes in rat liver. This soon led to the discovery in 1955 of the lysosome, an organelle in which are located all the most important degradative enzymes of the cell, such as phosphatases, nucleases and proteases. De Duve and his collaborators also demonstrated that the lysosomal enzymes existed in a latent state, but could be activated by physical or chemical injury to the cell or to the isolated particle. This observation has led to the publication of several monographs and thousands of papers on the important role of lysosomes as the central element of an "intracellular digestive tract" involved in turnover of cellular components-an indispensable function during cellular differentiation, development of an immune response, carcinogenesis and cell death. Of all the numerous discoveries by these three Nobel laureates, none has more potential value in medicine and pathology than the lysosome. The full realisation of its potential will, however, depend on determining whether altered lysosomal function is a cause or a consequence of the diseased cell.

In the past few years, de Duve, who has occupied a unique dual position at the University of Louvain and at the Rockefeller University, has also been responsible for the discovery of the peroxisome (whose function in vivo is as yet hard to assess) and for the application of the zonal ultra-centrifuge rotor to subcellular fractionation. Perhaps his most outstanding contribu-

tion to cell biology is his strict adherence to precise quantification and establishing 'balance sheets' for enzymes and other cell components derived by subcellular fractionation, a concept unfamiliar to classical cytologists before Claude's pioneering studies. His elegant use of enzyme markers has led not only to the discovery of the lysosome and the peroxisome but to engendering modern "enzyme cytology".

George Palade, a native of Rumania, was also influenced by Claude when he arrived to work at the Rockefeller Institute in the 1940s. Soon after playing his part in developing a better procedure for isolating mitochondria, Palade innovated techniques for fixation of tissues and subcellular fractions for electron microscopy which have now become standard throughout the world. This enabled him to propose a double membrane model for mitochondria, but by the mid-1950s he turned his attention to "microsomes".

With K. Porter he showed that this subcellular fraction was derived from the endoplasmic reticulum, an intricate network of intracellular membranes and ribosomes. In a fruitful and long lasting collaboration with P. Siekevitz, he provided the first direct confirmation that the ribosome was the site of protein synthesis in the cell. They also showed that active ribosomes existed both as free particles and in a form, predominant in protein secreting cells, in which these are attached to membranes. (Such membranes themselves have since been recognised to be the principal site of metabolism and detoxication of drugs, hormones, carcinogens and so on in the liver.) Students of molecular biology often fail to realise that the foundations for the spectacular success with cell-free preparations from E. coli in understanding the process of translation of genetic information were laid down by the work on rat-liver ribosomes in the laboratories of Palade and Zamecnik.

In the 1960s Palade's group became more and more interested in secretion of proteins and, in a series of elegantly designed and executed experiments involving the pancreas, established that proteins for export from the cell are exclusively synthesised on ribosomes bound to the membranes of the endoplasmic reticulum and not on free polyribosomes. They then described them vectorial passage of the newly snythesised protein into vesicles of "smooth" (ribosome-free) endoplasmic reticular membranes followed by their entry into the Golgi apparatus which would be moving towards the periphery of the cell. Most recently, Palade has turned his attention to the biogenesis of membranes and has proposed the mosaic pattern of arrangement of membrane components.

Finally this year's Nobel Prize highlights an extraordinary success story of research-the modern bio-medical Rockefeller University.

JAMSHED R. TATA

# Slowing energy growth without tears

by Colin Norman, Washington

Environmentalists, opponents of nuclear power and scientists working on energy-saving technologies got some good news recently. A massive study, funded by a grant of £4 million from the Ford Foundation, concluded that it may be possible to meet energy demand in the United States for the next 25 years without enlisting further help from such troublesome sources of power as nuclear reactors, offshore oil, oil shale and strip-mined coal from the Rocky Mountains.

The key to that sanguine prediction can be summed up in one word: conservation. But a good many people have already indicated that they don't believe it, and the Mobil Oil Corporation has published an advertisement in the New York Times to say so.

Called the Energy Policy Project, the study has one over-riding messagethat the United States has a wide variety of energy policy options available and need not be locked into a madcap development of all its domestic energy resources in order to become independent of Middle East oil supplies. In fact, the study argues that such a policy, which was adopted by the Nixon Administration and which has not changed much under President Ford's stewardship, will be inordinately expensive and environmentally destructive.

The most urgent task, the study suggests, is for the government to adopt a set of strong controls to reduce energy demand. Compared with the weak homilies dished up by President Ford during his recent economic message to Congress, when he exhorted his fellow countryman to drive less, wear lapel badges bearing the letters WIN (for Whip Inflation Now) and not to waste food, the Energy Policy Project's recommendations for energy conservation look pretty tough. But, for a country which wastes as much energy as the United States, they shouldn't be too difficult to take.

In essence, the study says that the growth in energy consumption, which has been racing away at about 4.5% in the past few years, can be cut to 2% if the government applies a strong enough hand. Furthermore, contrary to the dire predictions of some economists and industrialists, the study argues that it would be feasible to reduce energy growth to zero by the 1990s without plunging the country into economic stagnation. The four steps which the study says should be taken immediately are:

Energy prices should be allowed to

rise by eliminating subsidies to industry, by imposing pollution taxes on energy producers and by levying extra tariffs on oil imports.

- New cars should meet compulsory fuel economy standards so that the average American car would get 20 miles to the gallon by 1985. At present, the average gas-guzzling behemoth consumes a gallon of petrol every 14 miles, and some of Detroit's creations boast around eight or nine miles per gallon.
- Strong governmental measures should be taken to put a stop to the construction of buildings which have appalling heat losses. This could be done, the study reckons, by raising federally recommended standards and easing credit terms for making energy-saving modifications to existing buildings.
- Federal funding for energy research and development should be channelled more towards energy-saving technologies, and incentive should be given to to industry to apply the technology.

Adoption of those policies, coupled with some good propaganda in support of energy conservation (rather than the ludicrous statements of Nixon earlier this year when he prononuced the energy crisis over), would have the desired effect of slashing rates of energy growth in half, the study reckons. And that would mean that energy demands could be met over the next 10 years without any major new commitment to four controversial sources of supply-increased imports of oil, development of oil shale and coal deposits in the Rocky Mountains (where it is difficult to reclaim the land), nuclear power, and offshore oil drilling along the Atlantic and Pacific coasts and in the Gulf of Alaska.

Even so, energy consumption would increase by a total of about 28% by 1985, with the result that new oil supplies would have to come from the North Slope of Alaska and from secondary and tertiary recovery from existing wells, that coal production must be stepped up from deep mines and from strip mines in areas where reclamation is possible, and that electric power plants which are already being constructed—including nuclear reactors—will have to be brought on line.

But after 1985 it is a different story. If energy use continues to grow even at the reduced rate of 2% a year, at least two of those troublesome sources of supply will have to be opened up. But the point is that by adopting energy conservation measures now, the government can buy itself 10 years in which to choose among the various supply options, on the basis of thorough study of the possible environmental consequences. And, if it is decided that none of them is acceptable, the study says that more stringent conservation

measures could be taken to move the conutry towards zero energy growth by the 1990s.

It should be pointed out, however, that the Energy Policy Project's analysis flies directly in the face of two key assumptions underlying much of industry's-and also the Administration's -approach to energy planning. First, and most important, the study rejects the notion that energy growth and economic growth march hand-in-hand so that cutbacks in energy demand can only be accomplished at the expense of a healthy economy and a high standard of living. And second, the study explicitly states that laissez faire market economics are simply not good enough to regulate energy prices—the government must take an active role in the marketplace.

As for the first notion, according to the Energy Policy Project's director S. David Freemen, who was also energy adviser to Presidents Johnson and Nixon, "energy growth and economic growth can be uncoupled". In fact, the study concludes that cutting energy growth to 2% a year is a more attractive economic option than letting consumption rip at its historic levels. For a start, capital requirements for the energy industry will be \$300,000 million less over the next 25 years than they would be if growth is not curbed. The study also suggests that a gradual reduction in energy growth will actually increase employment because higher prices for energy will tend to substitute labour for energy in industrial processes. Furthermore, apart from the energy industry, industrial outputs will be virtually the same in conditions of reduced energy growth between 1985 and 2000 as they would if recent energy consumption trends were maintained.

As far as zero energy growth is concerned, that would require a strong governmental hand on the tiller and some changes in life style, but again the study predicts that the effects on the economy need not be dire. Such devices as a gradually increasing energy sales tax, expansion of urban mass transit systems, upgrading of rail services and greatly stepped-up research and developmental programmes would be required. The key will be gradual transition to a zero energy growth economy, to avoid major disruptions, and the study says it can be done at the expense of only a very small reduction in the growth of the gross national product.

The study prophetically warns, however, that "merely to discuss 'zero energy growth' is to unleash a torrent of indignant advertising paid for by major industrial interests which benefit from growth in energy consumption".

A Mobil advertisement published on the same day as the EPP report tells its readers that the report recommends substituting bicycles for cars, and that it would "move more than 1,000,000 people a year to new communities where they would work at the jobs planned for them by the government. The advertisement recommends elimination of energy waste (which it neglects to define), urges the development of new energy resources immediately and suggests that some environmental regulations should be relaxed. Without energy growth, Americans would "sacrifice their living standards", the advertisement implies.

Such sentiments can be found within the covers of the report itself, however. Before being published, the report was circulated to members of the Energy Policy Project's Advisory Board—a collection of individuals from industry, academe, environmental organisations and government—and their views appear as an appendix to the study. The nature of their criticisms is fairly well determined by who they represent.

Thus, Michael McClosky, Executive Director of the Sierra Club, takes the study to task for not recommending negative energy growth, and for being too timid in discussing the environmental consequences of high energy growth. Donald C. Burnham, Chairman of Westinghouse Electric Corporation, disagrees with the suggestion that energy growth and economic growth can be uncoupled. The assertions to that end are "totally unsupported by the facts", he says, and the changes proposed "would result in substantial social upheaval, as well as economic stagnation". But the most outspoken criticisms are offered by William P. Tayoulareas, President of Mobil, who says that the report is distorted and offers a recipe for economic disaster.

Be that as it may, will the study have any effect on government policy? The Administration's attitude towards energy conservation, as stated by Mr Ford in his economic message, is that it is clearly a good thing but that at this stage it should be voluntary. Mr Ford said that he hoped consumers and industry would be able to cut back enough to wipe a million barrels of oil a day off the import side of the trade ledger by 1976 and warned that some mandatory controls would have to be applied if voluntary conservation doesn't work. But he specifically rejected a recommendation from his chief energy adviser that a 30% tax should be slapped on petrol, and Congress would be extremely reluctant to take politically sensitive steps to allow energy prices to rise.

The over-riding policy remains as stated often by President Nixon—that domestic energy resources should be developed as rapidly as possible to offset oil imports.

IT was just a year ago that former President Nixon launched Project Independence with a rhetorical flourish and directed the Federal Energy Administration (FEA) to draw up a policy which will make the United States self-sufficient in energy supplies by 1980. Called the Project Independence blueprint, the FEA's plan will be published early in November, but with Nixon's original timetable long ago declared impossible, it represents more a discussion of options than a blueprint for self-sufficiency.

According to conversations with several energy officials and Congressional sources, the study's chief message is that the United States will have to rely on imported oil to meet its energy demands for at least the next decade, and probably for long after that.

Unlike the Ford Foundation study, the FEA blueprint does not suggest that decisions on whether or not to develop controversial domestic energy resources can be put off for a decade, but it does nevertheless put forward some ideas for energy conservation.

First, however, the blueprint suggests that if energy prices remain at present inflated levels, this alone could depress demand and cause the growth in energy consumption in the United States to drop to about 3% a year by 1985. In addition, measures such as mandatory fuel economy standards for new cars, credits for

insulating buildings and incentives for industry to use energy-saving technologies could bring the growth in consumption close to the 2% level recommended in the Ford Foundation study, the FEA reckons.

One reason why the United States is unlikely to stop importing oil in the near future, the study suggests, is that there is only a limited possibility for substituting some of the country's massive deposits of coal for oil. Such a substitution has been vigorously recommended both by former President Nixon and by President Ford, but the FEA analysis points out that only in electricity generation can coal replace oil to a large extent. Consequently, the study predicts that coal consumption will perhaps double by 1985, where as most previous forecasts have suggested that production will be tripled during the next decade. and that oil imports will be needed to meet demand at least until 1985. even with extensive drilling off the Atlantic and Pacific coasts and in the Gulf of Alaska.

The FEA study has some cautionary things to say about strip mining for coal in the arid western regions, suggesting that it will be environmentally destructive and that the coal will in any case contain large quantities of uranium, which could prove to be a health hazard. Similarly, the study pours cold water on the prospects for exploration of oil shale.

# Plans for two more Dutch satellites

from Arie de Kool, Rotterdam

EVEN though the first Dutch satellite, ANS, did not achieve its intended orbit, both astronomers and technicians are in good spirits because the instrument nonetheless works well. This is supposed to prove that Philips and Fokker-VFW may now regard themselves as able space companies. Astronomers are busy reprogramming their computers to make full use of the new orbital parameters.

Such success deserves to be continued—reasons the Dutch National Institute for Aerospace Development, which was established to promote industrial activity in the field. So it proposes two further satellites, both bigger than ANS, and too large to be built within the present decade or launched by a Scout rocket.

'Phase A' preparatory studies and preliminary design studies have been completed for the first satellite, another one devoted to astronomy, in fact an advanced infrared telescope.

The money is supposed to come from the Ministry of Economic Affairs and the Science Ministry. "After all, one should not expect that industry will be prepared to pay for a satellite it did not ask for", said one official of the Economy Department.

The second proposal is for an Earth resources satellite, with the principal objective of plant disease recognition. Most of the money for this one would have to come from the Department for Development Aid. "One of the main problems to be overcome is to convince the developing countries that they do have an interest in cooperation with a neutral country like Holland in this field", said the same government official

A group of scientists has, however, taken issue with these propositions. They feel that other fields of science take priority over space research and they are particularly convinced that remote sensing techniques, if at all useful, can only serve the owners of large monoculture plantations, not the small farmers who should, they say, be considered as the backbone of the developing countries.

# news and views

# Earthquakes predicted

In 1910, H. F. Reid, student of the great San Francisco earthquake and originator of the elastic rebound theory, wrote (in The California Earthquake of April 18, 1906, Carnegie Institution of Washington, 1910): "As strains always precede the rupture and as the strains are sufficiently great to be easily detected before the rupture occurs, in order to foresee tectonic earthquakes it is merely necessary to devise a method of determining the existence of the strains; and the rupture will in general occur in the neighborhood of the line where the strains are greatest, or along an older fault-line where the rock is weakest". Unfortunately, as Brune (Eos, 55, 820; 1974) has recently pointed out, Reid's optimistic assessment, though based on an earthquake model which is generally consistent with modern ideas, contains a flaw which severely constrains the accuracy of any prediction method. For an earthquake is a 'critical limit phenomenon' whose critical limit is influenced by a variety of factors in unpredictable ways. A partial analogy might be the behaviour of a strained wire made of inhomogeneous material. If the load producing the strain is gradually increased the wire will undoubtedly break, but when and where will only become apparent when it is too late. If the single wire is replaced by a bundle of wires (faults) with diverse properties, even the line along which the first break (earthquake) occurs will be unknown in

This inherent difficulty goes some way towards explaining why, 64 years after Reid's statement, reliable earthquake prediction has not yet been achieved. Certainly the lack of success is not for want of effort. Conscious of their extreme vulnerability, the Japanese began to take a serious interest in earthquakes as early as the late nineteenth century when eminent seismologists such as Milne and Oldham were persuaded to make Japan their natural laboratory. More formally, the Imperial Earthquake Investigation Commission was established to encourage seismic studies in the wake of the 1891 Nobi earthquake (magnitude unknown, 7,270 killed); and the 1923 Tokyo earthquake (magnitude 8.3, 99,330 killed) gave the political impetus necessary for the formation of the Earthquake Research Institute at the Tokyo Imperial University. Not all the work which followed was aimed directly at earthquake prediction, although there is no doubt that prediction was the ultimate aim. But in 1961 prediction became a collective research goal when a new group dedicated to that end produced the classic report, Prediction of Earthquakes-Progress to Date and Plans for Further Development. Here the Japanese spelled out their basic philosophy that successful prediction would probably only emerge from long term monitoring of many different aspects of the seismic environment. Specifically, they proposed a 10-year scientific programme involving tide-gauge observations, levelling surveys, repeated triangulation, continuous observation of crustal deformation, micro-earthquake studies and geomagnetic

So far this work has not paid off in any significant way, although it has been responsible for one minor success. During the Matsushiro series of earthquakes which struck central Japan during 1965–1966, a combination of various monitoring data and intelligent guesswork enabled Japanese scientists to give some warning of the particularly violent

activity of April and August 1966. But it is ironic that, in spite of this success and in spite of Japan's long-term commitment to earthquake studies, the current wave of prediction stems from a phenomenon to which they gave comparatively little attention. In 1962, Kondratenko and Nersesov (Trudy Inst. Fiz., Zemli, 25, 130; 1962) discovered that the velocity of crustal P waves increased after moderately large earthquakes in the Tadjikistan region of southern central Asia. They had analysed over 800 travel-time curves from foreshocks and aftershocks of earthquakes with magnitudes 5 or greater and concluded that the average P wave velocity was 5.3 km s<sup>-1</sup> before the main shocks and 6.3 km s<sup>-1</sup> afterwards.

For six years this discovery remained unknown outside the Soviet Union until Savarensky (Tectonophysics, 6, 17; 1968) reviewed the data in English at a conference in Switzerland. Rikitake's (Earth Sci. Rev., 4, 245; 1968) initial response to this revelation was to imply doubt about the validity of the data on the grounds that a P wave velocity change of 15% would correspond to a change in elasticity of 30%. But more results soon followed. Semenov (Izv. Akad. Nauk. SSSR Phys. Solid Earth, 4, 245; 1969), for example, showed that prior to earthquakes in the magnitude range 3-5, the P wave-S wave velocity ratio  $(V_P/V_S)$ decreased by about 6% and then increased again to its normal value just before the main shock. The phenomenon was then taken up by scientists in the United States. A few years later, Aggarwal et al. (Nature, 241, 101; 1973) were able to report that they had discovered VP/Vs decreases of up to 13% preceding New York earthquakes in the magnitude range 1-3. Soon after, Whitcomb et al. (Science, 180, 632; 1973) reported a precursory V<sub>p</sub>/V<sub>s</sub> reduction of 10% for the much larger (magnitude 6.4) San Fernando earthquake of 1971, and showed that the reduction was due largely to changes in  $V_P$ .

By this time a remarkable change of attitude among United States seismologists was apparent. Before the early 1960s most of them had tended to fight shy of any connection with earthquake prediction because of what Oliver (Tectonophysics, 9, 283; 1970) termed its close association with "seers, mystics, fortune-tellers and the like" and the "great publicity . . . given to earthquake predictions based largely on quackery of some sort". But three parallel developments during the 1960s brought earthquake prediction a "great increase in respectability". First was the growth of plate tectonics which gave a new understanding to the role of earthquakes in the global context and thus led to an upsurge of interest in the phenomenon (although by drawing attention to the number of quite different environments in which earthquakes occur, it also seemed to suggest that the prediction problem was even more intractable than had previously been supposed).

The second development, again not directly concerned with prediction, was rather more violent. In 1966, Evans (Mountain Geologist, 3, 23; 1966) concluded that a mysterious series of earthquakes which had been plaguing the Denver, Colorado area for the previous few years was directly related to the injection of fluid into a disposal well at the Rocky Mountain Arsenal some 20 km away. In other words, these were man-made earthquakes; and Evans's explanation of them revived interest in other sources of artificial earthquakes, particularly the shocks thought to be associated with the filling of reservoirs (Carder, in Engineering Geology Case Histories Number 8, Geological Society

of America, 1970). The discovery of man-made earthquakes inevitably raised the question of how they were produced; and this led to a basic understanding of the part played in earthquake mechanisms by fluids. Meanwhile, several workers, beginning with Mogi (Bull. Earthquake Res. Inst., 40, 125; 1962) and continuing with Brace (Tectonophysics, 6, 75; 1968) and Byerlee (J. geophys. Res., 72, 3639; 1967) and others, had been investigating the behaviour of rocks under stress in laboratory conditions, and had come to appreciate the importance of fracturing in rocks in earthquake-prone regions.

All three developments finally came together during 1972-73 in physical models proposed by Nur (*Bull Seismol. Soc. Am.*, **62**, 1217; 1972), Scholz *et al.* (*Science*, **181**, 803; 1973) and Whitcomb *et al.*—models which differ only in

detail. In that of Whitcomb et al., for example, the pores and cracks in the initially unstrained rock are saturated with fluid. As the stress builds up prior to an earthquake the rock increases in volume (dilates), leading to a decrease in pore fluid pressure and ultimately to a situation in which the pore and crack volume exceeds the fluid volume. In this undersaturated state the rock voids partially contain vapour, which reduces the overall bulk modulus,  $V_P$  and hence  $V_P/V_S$ . The initial effect of the dilatancy is thus to delay the onset of the earthquake (dilatancy strengthening); but fluid from outside the dilatant volume gradually flows in, returning the volume to its saturated state, increasing  $V_P/V_S$  and decreasing the fracture strength until the earthquake occurs.

With a promising prediction technique to be developed

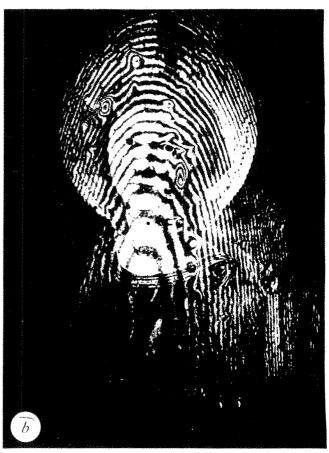

Fig. 1 a, Santa Caterina by Pier Francesco Fiorentina; b, damaged areas indicated by holographic interferometry.

THE detection of incipient damage and deterioration in oil paintings is important for their conservation and restoration. A technique developed by Italian scientists will make this easier in future. S. Amadesi et al. (Applied Optics, 13, 2009; 1974) used holographic interferometry to study paintings on wooden panels. Such pictures have several layers of primer underneath the paint, and these are liable to peel away from the wood. In the early stages the detachment is easier to repair but harder to detect.

Amadesi and his colleagues realised that if a painting were warmed, detached regions would disperse heat at a lower rate than the surrounding areas, so their temperature rise and thermal expansion would be greater.

### Painting holograms

from John Walker

These changes could then be observed by taking two holograms at fiveminute intervals, using a laser. The principle is like superimposing two almost identical photographs: any differences are immediately apparent. The advantage of holograms is that much smaller differences are observable.

In a test run on a laboratory specimen—primed poplar wood—plastic slivers under the primer were easily located. The crucial test was made on the fifteenth century Italian panel painting shown in Fig. 1a. The change in room temperature during

the five minutes between the two holograms was sufficient to indicate some detachments, but localisation was poor. So the painting was warmed to 40° C (not hot enough to cause damage). Many more detachments were then observed, and they were better defined. This is shown in Fig. 1b. The 'contour lines' superimposed on the image are interference fringes, and the kinks indicate detached regions. In undamaged paintings these distortions of the fringe pattern do not occur.

The method can also be applied to frescoes and paintings on canvas. It will be increasingly useful, not only to locate detachments already present, but to monitor undamaged paintings to make sure they stay that way.

and an attractive explanatory physical model to be tested, the expected rapid increase in the number of prediction studies has occurred: at least 10 new reports have appeared during the past three months alone. Mazzella and Morrison (Science, 185, 857; 1974), for example, have gone some way towards confirming the view put forward by Scholz et al. that  $V_P/V_S$  changes should not be the only earthquake precursor attributable to the dilatancy effect. They find that in the middle of April 1973 the resistivity in the vicinity of a strike-slip section of the San Andreas fault south of Hollister (California) suddenly decreased by 10%, subsequently rising again by the end of May to 10-15% above its initial level and dropping back again to that level by 15 June. On 22 June, a magnitude 3.9 earthquake occurred in the region at a depth of 9.5 km. Calculations suggest that the observed variations could have been caused by either a small resistivity change over a large volume or a large change over a small volume; for example, an 80% resistivity change in a region 4 km wide and 2-6 km deep would both explain the data and be physically possible. But either way, as resistivity changes are known to reflect changes in rock porosity and the degree of water saturation, the link with dilatation is not difficult to find.

Although this is the first time that precursory resistivity changes have been associated with strike-slip faulting, the phenomenon is not strictly new in that similar changes of up to 20% were observed by Barsukov (Tectonophysics, 14, 273; 1972) prior to thrust-type earthquakes in the Garm area of the Soviet Union. But what is new is the discovery by Bufe et al. (Geophys. Res. Lett., 1, 221, 1974) that microearthquakes occurring within 10 km of the epicentre of the 1972 Stone Canyon shock (magnitude 4.6) had anomalously large (by 25%) mean focal depths for 60 days preceding the event. Bufe and his colleagues note that it is possible that seismicity really did migrate vertically during this period; but on balance they conclude that the effect is caused by a dilatancy biassing of the foci corresponding to a 10-15% decrease in seismic velocity wtihin a local shallow region.

Moreover, as the Stone Canyon earthquake epicentre fles close to the San Andreas fault within a few kilometres of the area studied by Mazzella and Morrison, this is further evidence of precursors being associated with strike-slip faulting. Last year, doubt about the existence of this phenomenon was expressed by McEvilly and Johnson (Science, 182, 588; 1973) who concluded that there were no P wave changes prior to the 1972 Bear Valley (California) earthquake, although Robinson et al. (Science, 184, 1281; 1974) were later able to refute this suggestion and Wyss and Holcomb (Nature, 245, 139; 1973) had earlier demonstrated the existence of precursors to the strike-slip Matsushiro events. In short, it is now certain that strike-slip faulting is no less susceptible to premonitory indicators than is thrust faulting. This being so, it is clear that the absence of a P wave residual anomaly in central California, now reported by Wyss (Nature, 251, 126; 1974), cannot be attributed to any general lack of precursors to strike-slip tectonism. Instead, therefore, Wyss has interpreted his data to mean that between San Francisco and Parkfield (California) there will be no magnitude 7+ earthquake during the next 7 years and no magnitude 8+ earthquake during the next 25 years. Here is a true prediction, the accuracy of which can only be judged by future events.

But to return to restrospective studies, Wyss and Johnston (J. geophys. Res., 79, 3283; 1974) report that the 1966 Seddon (magnitude 5.8) and Gisborne (magnitude 6.1) earthquakes of New Zealand were associated with P wave changes which began 360 days and 550 days before, respectively. By contrast, McGarr (Science, 185, 1047; 1974) shows that a magnitude 3.8 tremor occurred in South Africa in March 1973 was preceded by no such changes. So is there a problem here, or is the South African shock a

special case? Wang (Nature, 251, 405; 1974) has an ingeneous explanation for contradictions of this sort, based on results obtained last year by Gupta (J. geophys. Res., 78, 6936; 1973). Gupta showed experimentally that when sound waves are transmitted through rock (limestone) containing oriented dilatant microcracks, there is little variation in velocities or velocity ratios in directions parallel to the cracks but large variations perpendicular to them. And apparently unaware of Gupta's work, Anderson et al. (1. geophys. Res., 79, 4011; 1974) have now shown theoretically that fluid-filled ellipsoidal cracks should produce the same effect. Wang's point is thus simple; assuming (and it seems reasonable to do so) that the dilatant cracks lie in a single . direction (probably parallel to the Earth's free surface), whether or not  $V_P$  and  $V_P/V_S$  changes are detected will depend on the direction in which the observed waves are travelling with respect to the cracks. Unfortunately, McGarr, aware of the Anderson et al. article before publication, shows that this cannot be the explanation for the lack of precursors in South Africa. On the other hand, the South African event was not an earthquake but a mining tremor; and so there may after all be good reasons why it can break the rule without destroying the principle.

So where does all this leave earthquake prediction? The enswer seems to be, in quite a healthy state. There are few, if any, genuine contradictions; and the fact that all precursors obey the same time law, with precursor time related logarithmically to earthquake magnitude, strengthens the view that they may be attributed to the same dilatancy mechanism. But routine prediction is not yet possible nor even likely to become so in the near future. The only certain prediction is that in the coming months much will be said on the subject.

Peter J. Smith

# Control of cell growth by the cyclic nucleotide seesaw

NORMAL fibroblasts in tissue culture can exist in two growth states, one of rapid proliferation (growing) and one of relative quiescence (resting). Transition from the resting to the growing state can be produced by a number of stimuli including growth factors present in animal serum, by insulin and by proteases. Once growth is initiated a whole range of events takes place including stimulation of transport of molecules into the cell, increases in protein and RNA synthesis and eventually DNA synthesis. This sequence of events was termed the 'pleiotypic programme' by Tomkins and his collaborators (Nature new Biol., 232, 206; 1971), and a knowledge of how these events are related is fundamental to the understanding of growth control in animal cells.

Since hormones such as insulin and factors such as serum proteins are not thought to enter the cell, Tomkins suggested that they interacted with the cell membrane to modulate the production of chemical mediators that regulate events within the cell. As cyclic AMP has been shown to be the second messenger of many hormones which act at the cell surface, it was only natural to look for changes in the compound in cells stimulated to grow. A substantial drop in the concentration of cyclic AMP was observed within five minutes of the stimulation with serum of the growth of mouse fibroblasts, concomitant with a large increase in the transport of various compounds into the cell: some twenty hours later cell division occurred. If prostaglandin E1 (which raises intracellular cyclic AMP concentrations) was added together with serum some of the transport changes and cell division were inhibited. This led to the

supposition that the fall in cyclic AMP concentrations was in some way a trigger initiating the 'pleiotypic programme'.

But it soon became apparent that falls in cyclic AMP did not invariably accompany induction of growth. When lymphocytes were treated with the mitogen concanavalin A no change was observed in cyclic AMP concentrations but the concentration of the related nucleotide cyclic GMP rose (Goldberg et al., Proc. natn. Acad. Sci., U.S.A., 69, 3024; 1972). This observation led Goldberg to propose that growth was regulated by the balance of cyclic AMP and cyclic GMP in the cell, high cyclic AMP: cyclic GMP ratios being associated with the proliferative state. A recent paper by Rudland (Nature, 251, 417; 1974) documents changes in cyclic AMP and cyclic GMP in a number of cell lines. It shows that non-transformed fibroblasts exhibit large differences in the concentrations of cyclic AMP and cyclic GMP and in the cyclic AMP: cyclic GMP ratios for growing and quiescent cells but that no such difference occurs in transformed fibroblasts. This suggests that there may be fundamental difference in the control of cyclic nucleotide concentrations between normal and transformed cells. In any event low cyclic AMP: cyclic GMP ratios are associated with proliferation, high ratios with quiescence. This concordance of fact with theory is somewhat marred by a recent report that no changes can be detected in cyclic nucleotide concentrations in chick embryo fibroblasts in several different growth states or when the cells are transformed with a number of viruses (Hovi, Keski-Oja, and Vaheri, Cell, 2, 235; 1974). Whether this reflects differences in the mechanism of growth regulation in different cell types or a defect in the hypothesis of growth control by reciprocal changes in cyclic AMP and cyclic GMP concentrations is not clear at the moment.

Correlations of the concentrations of cyclic nucleotides with growth pattern in the cell are unsatisfactory in that they do not prove that the nucleotides actually control growth processes within the cell. Two approaches to this problem have been attempted. One is to add cyclic nucleotides exogenously to attempt to mimic or block growth stimulation by serum, and the other is to isolate simple factors that will specifically alter one of these nucleotides within the cell. In recent series of papers, Rudland and Seifert and collaborators report results of both approaches They reasoned that if an increase in cyclic GMP concentration was a signal for cell division then by adding cyclic GMP exogenously it might be possible to persuade quiescent

cells to divide. The experiment (Nature, 248, 138; 1974) showed that of a number of nucleotides tested only cyclic GMP and its analogues or cyclic IMP were partially effective in promoting division whereas serum can stimulate all the cells to divide. Experiments where serum stimulation is blocked by raising cyclic AMP concentrations have been more successful (Nature, 251, 417; 1974). Almost the entire effect can be overcome using prostaglandin E1, but experiments using high doses of potentially toxic compounds for long periods should be interpreted with care, especially if growth inhibition results.

Using the other approach Rudland took advantage of the purified protein factor isolated by Gospodarowicz from bovine pitditary (Nature, 249, 123; 1974). This factor, termed fibroblast growth factor (FGF), together with hydrocortisone and bovine serum albumin can completely replace serum in its growth promoting activity in certain lines of BALB/c 3T3 cells. What is particularly interesting is that FGF initiates the pleiotypic programme without a significant fall in cyclic AMP concentration (Nature, 250, 791; 1974) -only a large change in cyclic GMP occurs. Furthermore studies on isolated membranes from BALB/c 3T3 cells show that FGF will specifically stimulate guanyl cyclase, leaving adenyl cyclase unaffected. These data strongly suggest that increases in intracellular cyclic GMP concentrations may alone be sufficient to initiate growth without concomitant decreases in cyclic AMP. But it still remains possible that FGF initiates some general membrane change leading to cell growth (such as promoting nutrient uptake) and that cyclic GMP remains merely a correlate of such a change. Only by further dissection of the system by isolation of other factors which affect cell growth in a defined way can the problem be understood.

ROBERT SHIELDS

# Multiple transfer processes in heavy ion reactions

from P. E. Hodgson

EXPERIMENTAL studies of the inelastic scattering of heavy ions have revealed a pronounced oscillatory structure in the angular distributions, and this has been explained as an interference effect between the direct inelastic scattering and one-step transfer inelastic scattering. Such effects are particularly strong when the interacting ions differ only by the transferred nucleon, for example in the reaction

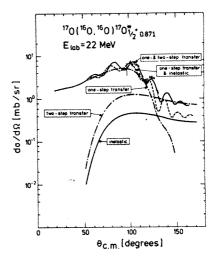

Fig. 1 Differential cross section for the 170(160, 160')170\* (½+, 0.871 MeV) reaction at 22 MeV compared with coupled channel calculations of the direct inelastic, one-step transfer and two-step transfer processes, both individually and combined together.

 $^{17}0(^{16}0, ^{16}0')^{17}0*$ ; so that by the transfer process they effectively exchange their identities (Nature, 248, 735; 1974). Though calculations with this model give a good qualitative account of the data, there remain significant discrepancies, and now Bauer and Wolter (Phys. Lett. 51B, 205; 1974) have shown that these result from the contribution of double transfer processes. Such processes are familiar in the atomic scattering of ions, where electrons are transferred back and forth many times, and some evidence for them has been found in nuclear processes such as the scattering of alpha particles by 'Li (Nature, 246, 14; 1973).

Bauer and Wolter studied the inelastic scattering reaction <sup>17</sup>0(<sup>18</sup>0, <sup>18</sup>0')<sup>17</sup>0\* to the ½ state of <sup>17</sup>0 at 0.871 MeV at several incident energies. They set up a system of coupled wave equations that enabled them to calculate the cross sections of the direct inelastic scattering together with the contributions due to the single and double transfer processes.

The contributions of these processes are compared in Fig. 1 with the experimental cross section for an incident energy of 22 MeV. The direct inelastic process alone gives a smooth angular distribution with its main strength in the backward hemisphere. The onestep transfer alone also gives a smooth distribution but has a much higher cross section and is broadly peaked around 100°. These two processes together interfere to give an oscillatory distribution that agrees qualitatively with the experimental data, but shows a significant phase difference. The twostep transfer alone gives a smooth distribution very similar to the direct inelastic process, but with a higher overall cross section, and when it is combined with the direct inelastic and the one-step transfer it gives a distribution that agrees very well with the experimental data. The inclusion of the two-step process has thus essentially accounted for the phase difference in the previous comparison without this process.

The full calculation with the one and two step transfer processes as well as the direct inelastic scattering was repeated for some other energies and they were seen to give a very good overall account of the change of the cross section with energy. It is likely that the small discrepancies that remain can be accounted for by higher order transfer processes. The calculations also give the cross sections for elastic scattering, and these agree well with the experimental data.

# Flares and spots on dwarf M stars

from R. A. E. Fosbury

PROBABLY the most common selfluminous objects in the Universe are the dwarf M stars: stars which have a mass less than a few tenths that of the Sun but a luminosity which is smaller by a considerably larger factor. Their faintness has, until quite recently, resulted in neglect by observers and theoreticians alike. But this property is an advantage in the study of some curious phenomena which take place in their outer atmospheres. A major flare can increase the brightness of one of these little stars by more than five magnitudes (a factor of one hundred) for a period of a few minutes.

The high kinetic temperatures found in the solar chromosphere and corona are thought to result from the dissipation of a mechanical energy flux which has its origin in the hydrogen convection zone beneath the photosphere. The magneto-acoustic wave modes which are allowed to propagate upwards through the temperature minimum between the photosphere and chromosphere travel through regions of decreasing gas density until they are forced to dissipate their energy as heat through some form of shock. By analogy this form of non-radiative heating is believed to operate in all stars which have a significant convection zone near their surface, that is, those stars which have a spectral type later (cooler) than about F5. Another consequence of the outwardly decreasing density in a stellar atmosphere is the importance of any surface magnetic field in controlling the morphology above the height at which the gas and magnetic pressures are approximately equal. It is the resulting structural inhomogeneity which makes the quantitative study of the chromospheres of stars other than the Sun so difficult.

The existence of stellar chromospheres can be inferred from observations of spectral lines whose profiles show that the temperature increases outwards through part of their region of formation. The best known of these are the famous violet H and K lines of ionised calcium which can be detected in emission in a very large number of late-type stars. Even more useful chromospheric indicators are the analogous lines of ionised magnesium at 280 nm which are now being observed from balloon, rocket and satellite. A subset of the dwarf M stars, known as dMe stars, show also the Balmer lines of hydrogen in emission and it is from this subset that are drawn most, if not all, of the known flare stars.

The flare stars have now provided the clearest observational evidence so far of the existence of starspots. Observations of quasi-periodic brightness variations (outside times of flare activity) by Evans and Bopp at Texas and others have been interpreted as a rotational modulation caused by large dark areas drifting across the visible hemisphere. These spots can cover as much as 50 degrees in latitude and longitude but the actual sizes they derive depend to some extent on the temperatures assigned to them. One might naively think that the sizes of such surface inhomogeneities are fixed in some way by the pressure scale height in the atmosphere, the ratio of this quantity to the stellar radius being roughly constant along the main sequence. D. J. Mullan (Astrophys. J., 186, 1059; 1973) however has put forward the hypothesis that sunspots can be considered as convection cells of some type which extend to the bottom of the solar convection zone. In his latest paper (Astrophys. J., 192, 149; 1974) he extends this idea to the flare stars which, with their position lower down the main sequence, have envelope convection zones with a much greater radial extent. Since the ratio of spot diameter to depth has a minimum value of about two in his theory, he predicts that the diameters of spots should be greater in later spectral types. The predicted sizes are in good agreement with

When the convection zone is confined to a thin shell, as it is in the Sun, the dynamo-generated magnetic field is made up primarily of the higher order multipoles. As the convection zone becomes deeper, however, the lower order multipoles come to dominate until in a fully convective star the field should be mainly dipolar. Mullan suggests that this puts a lower limit on the mass, and hence luminosity, of stars which might be expected to show a rotational

modulation of brightness. If the field is dipolar with rotational and magnetic axes parallel then the spots would be expected to form symmetrically around the poles.

Mullan computes a model for a spot on the flare star YY Gem and estimates a surface field in the spot of about 20 kilogauss. Such large magnetic fields are probably generated by efficient dynamos driven by fast differential rotation. There is some evidence that tidal effects may be partly responsible for triggering the sudden release of energy contained in a magnetic field, resulting in a stellar flare.

### Macrophages eat their way into genetic control of immunity

from Robert Kerbel

MACROPHAGES seem to exist solely for the amusement of immunologists, enabling them to re-discover their importance about every five years. This predictable cycle has been upset by recent events, and one could say it's been a good year—or two—for the macrophage.

To begin with, it appears the macrophage has been restored to its position of being the principal aggressor cell in anti-tumour immunity systems (see for example Eccles and Alexander, Nature, 250, 667; 1974) after being temporarily eased off centre stage by the T cell. Then there was the work of Feldmann and colleagues which assigned a role to macrophages in antibody formation beyond the mere digestion and processing of antigen (Feldmann and Nossal, Transplantn. Rev., 13, 3; 1972); these authors reason that the surface of certain types of macrophage is the main site of T and B cell collaboration, by virtue of the highly cytophilic nature of an antigen-specific factor (IgT, as it is called) liberated by activated T cells, for the surface of macrophages.

But at least these are areas in which macrophages have always been thought to play a part, even if the importance of their role varied from one year to the next. A recent set of papers from the laboratory of J. G. Howard, however, now transports macrophages firmly into an area in which they were never seriously considered previously to have a role-genetic control of the immune response (Howard, Courtenay and Desaymard, Eur. J. Immun., 4, 453; 1974; and Weiner and Bandieri, Eur. J. Immun., 4, 457; 1974). The authors' model involved the use of so-called Biozzi 'high' and 'low' responder mice; these are two lines of mice (Ab/H and Ab/L) which were genetically selected

from outbred Swiss Albino stock for their respective high and low antibody responses to immunisation with sheep red blood cells (Biozzi et al., Annls Immun. Inst. Pasteur, Paris, 115, 965; 1968). Since the original studies with sheep erythrocytes, a number of reports has shown that this separate responsiveness is maintained when using just about any other antigen, including a few which do not require T cells to give a good response. This has gradually led to the view that the genetic difference in the two strains resides at the level of the B lymphocyte, resulting in a relative inability of Ab/L B cells to differentiate and proliferate to antibody-producing cells following contact with antigen.

The results of Howard et al. would seem to put this notion to rest. These authors showed that the antigens levan and dextran B1355, both of which do not require T cells (and both being highly branched polysaccharides), give equivalent antibody responsiveness in the two strains. Furthermore if a haptenic chemical grouping, DNP, was coupled to an antigen which normally gives separate responsiveness (polymerised bacterial flagellin or POL, in this case) then high and low responses to DNP were also obtained, whereas equivalent responses were obtained if the DNP was chemically coupled to levan. This indicates that there is nothing intrinsically defective or different in the ability of B cells with anti-DNP specificity to proliferate and make anti-DNP antibodies in the Ab/L strain. The 'defect' rather is, as the authors say, extrinsic to the lymphocyte population.

What then is the nature of this extrinsic difference? The paper by Weiner and Bandieri suggests that it may reside in the way antigens are handled by macrophages. When peritoneal macrophages were isolated from the two strains and cultured overnight, a striking difference in the morphological appearance of the cells became apparent: the majority of Ab/H macrophages were well spread out, with an irregular cytoplasmic outline and many extensions, whereas most of the Ab/L macrophages assumed a spherical conformation and lacked the many prolongations or extensions so characteristic of macrophages cultured on plastic surfaces. When the authors looked at the way macrophages handled a number of antigens which always give separate responsiveness in the two strains they found these antigens were taken up faster by Ab/L macrophages. Furthermore membranebound antigen disappeared rapidly from Ab/L macrophages whereas it persisted in Ab/Hemacrophages. Intracellular digestion of antigen was more rapid in the Ab/L macrophages and

this may be related to their containing higher levels of lysosomal enzymes.

Thus macrophages from the 'low' responders seemed, if anything, hyperactive. These differences were, however, not observed if the antigen tested with the macrophages was levan. The authors therefore speculate that this hyperactivity might render various antigens more poorly immunogenic in the Ab/L line. Whatever the explanation, it seems that macrophages can express genes which help control antibody responses in these strains.

It also may be of considerable interest to those studying the roles of macrophages in cellular immunity that the Ab/H and Ab/L strains give equivalent responses for virtually all types of such reactions thus far tested, including allograft responses, contact sensitivity to chemicals, and graft-versus-host reactions.

# Species richness in geological time

from Peter D. Moore

A CONCEPT which has received widespread support among ecologists is that the species richness of a stable habitat increases steadily through geological time. The justification for such support can largely be traced back to the work of Southwood (J. Anim. Ecol., 30, 1; 1961) who demonstrated a positive linear correlation between the number of Quaternary subfossil records of various British tree taxa and the number of insect species associated with them. If one assumes that the antiquity and persistence of a tree is reflected by the abundance of its subfossil occurrences, then Southwood's work implies that the longer a tree has been present in these islands in any quantity, the more likely it is that many insect species will be associated with it. The finding suggests that the Quaternary time span has not been sufficient to saturate any tree's resources as an invertebrate microhabitat.

Other data have suggested that the relationship between species richness and time is asymptotic, richness rising rapidly at first, then levelling off. The time scale involved before saturation may be reckoned in decades or centuries rather than millenia. For example, Simberloff and Wilson (*Ecology*, **50**, 278; 1969) exterminated the invertebrate fauna of mangrove islands off the Florida coast and observed that reinvasion occurred in an asymptotic fashion over a relatively short period.

Since Southwood's results are so often used to justify the concept of geological time as a critical factor determining richness, Strong has now attempted to re-analyse Southwood's

data (Proc. natn. Acad. Sci., U.S.A., 71, 2766; 1974). Strong points out a logical inadequacy in Southwood's basic assumption, in that he confounds the antiquity of tree taxa with their past abundance and distribution. To resolve this confusion, Strong plots each of Southwood's tree taxa on a graph relating the logarithm of taxon range (estimated by the number of kilometre square samples in which it is now found) to the logarithm of the number of associated species (using Southwood's figures). The graph shows a strong positive linear correlation. He also found that the distribution of recently introduced taxa about the regression line is not significantly different from that of the native species. Thus recent introductions are saturated with insect species to the same extent as the natives: otherwise they would have fewer insect species than would be expected from a consideration of their area of occupation.

The conclusion from this work is that the area of distribution of a tree is more important as a determinant of its insect species richness than is its antiquity. Evidently the more abundant a tree species is now the more likely it is to have left many fossils in recent Quaternary sediments; since Southwood did not take into consideration the age of subfossil finds, it is not surprising that he found a positive correlation between fossil abundance and insect species richness.

It is unfortunate that Strong did not use more up to date information concerning the insect species richness of certain trees. For example the estimate for larch of about 15 species is far too low, but most values are probably underestimates and the general form of the relationship would probably not have been altered. Strong is wrong, however, on this basis to deny the assertion by May (in Stability and Complexity in Model Ecosystems, Princeton, 1973) that although species richness is well regulated on an ecological time scale the regulated level will increase in geological time. Strong has provided no information on what happens to species richness on a geological time scale except that any change in richness is of little statistical significance in comparison with shortterm changes. The variation of species richness over geological periods remains an area for conjecture.

### Correction

An error was introduced in the final drafting of the article "Oppression or Altruism in Insect Unions?" (Nature 251, 101; 1974). The (female) workers are of course diploid, like their sister queens, and not haploid as stated.

### review article

# Development of general relativity

S. Chandrasekhar\*

This article is based on an invited talk given at the 1974 annual meeting of the American Physical Society in Chicago on the occasion of the award of the Dannie Heineman Prize for Mathematical Physics, February 5, 1974. (The substance of this lecture has been published for private circulation in the Summer 1974 issue of The University of Chicago Magazine.)

In an invited talk at a meeting of this society which Freeman Dyson gave nine years ago<sup>1</sup>, he described the history of the development of the general theory of relativity in the following terms:

"Einstein's theory of gravitation took the world by storm in 1919 for two reasons. In the first place, there was the dramatic prediction of the displacement of star-images by the Sun's gravitational field, the organisation of eclipse expeditions to Brazil and Africa to make the very difficult observations that could test the theory, and the clearly positive outcome of the test. In the second place, there was the appealing philosophical character of the Einstein theory, starting with the postulate of a space-time continuum without any special framework of coordinates to label points of space-time with numbers, so that all the laws of physics should be statements which are true in any possible coordinate system.

To Einstein himself and to many other physicists of the 1920s, including Hermann Weyl and the youthful Pauli, it appeared that this beautiful and successful gravitation theory must be the model for the future development of physics. They expected that further extension of the two principles of Einstein, firstly the representation of physical reality as geometrical in nature, and secondly the insistence on general coordinate invariance, would lead to understanding of electromagnetism and of matter, the chief phenomena that remained outside Einstein's original theory. As is well known, these expectations proved false. The theory of matter and electromagnetism took a totally different direction with the advent of quantum mechanics in 1925. Everybody involved in the development of quantum mechanics forgot rather quickly about gravitation and assumed special coordinate systems without apology. Meanwhile the study of gravitation itself lost interest for physicists because nobody could think of any new observations or experiments. So the theory of gravitation gradually became detached from the rest of physics and was studied only by specialists."

Complementary to Dyson's last statement that the general theory of relativity lost its interest to the physicist because "one could not think of any new observations or experiments" is the statement, which one often hears now, that the renewed interest in general relativity during the 1960s is due to the emergence of new astronomical observations and new planned experiments bearing on the theory. I shall not presume to disagree with these statements. But I must confess that it is not clear to me why some very obvious questions were not asked of general relativity until fairly recently: questions whose

answers could well have contributed to an understanding of the theory itself as distinct from its bearing on possible observations or experiments.

I shall illustrate by some examples the kinds of questions that might have been asked.

### **Orbit of Mercury**

One of the first accomplishments of the general theory of relativity was to show that the trajectory of a test particle in the gravitational field of a central mass is a Kepler ellipse which precesses. The agreement of this predicted precession with that observed for the planet Mercury demonstrated that the theory had successfully met one of Einstein's three crucial tests. The comparison that was made is proper since the approximation of considering Mercury as an infinitesimal test particle in the gravitational field solely of the Sun is an extremely good one. It is well known, however, that in the framework of the Newtonian theory, two finite spherical masses will also describe Kepler ellipses, exactly, about their common centre of mass. On this account, it would be natural to expect that in the framework of general relativity these Kepler ellipses will, in a first non-trivial approximation to the theory, also precess; and, further, that the precession will be given by the same formula that is applicable to the case of an infinitesimal test particle except for the difference that the mass of the central body is replaced by some reduced mass. If these expectations should be justified, then their establishment in the framework of the theory cannot be very difficult. Nevertheless, only twenty years after the founding of the theory was the question asked and its solution attempted by Eddington and Clark, Einstein, Infeld, and Hoffmann, and Fock, independently.

### **Gravitational radiation**

Let me consider a second example. The principal reason why Einstein felt compelled to develop his general theory was, of course, the fact that the Newtonian theory is based on instantaneous action at a distance—a proposition that is contrary to the tenets of special relativity. On the general theory, gravitational forces are propagated with the velocity of light, and as a consequence it would be natural if the theory predicted the emission and propagation of gravitational waves by systems that are nonstationary. Simple considerations of a semiheuristic nature show, as Einstein in fact showed in 1918, that on a linearised version of the theory, gravitational radiation will be emitted by systems that are nonstationary; that such radiation will have a quadrupole character; and finally that the flux of such radiation will be proportional to the square of the third time derivative of the quadrupole moment of the system. Nevertheless, for some forty years serious theoretical doubts were entertained with regard to the reality of the predicted radiation. For example, in the Born-Einstein letters that have recently been published2 there is an undated letter

<sup>\*</sup>Enrico Fermi Institute, University of Chicago, 933 East 56th Street, Chicago, Illinois 60637.

from Einstein (there is circumstantial evidence that it was written in 1936) in which he wrote:

"Together with a young collaborator I have arrived at the interesting result that gravitational waves do not exist though they had been assumed a certainty to a first approximation. This shows that the nonlinear general relativistic field equations can tell us more or, rather, limit us more than we have expected."

Again in the last page of Infeld and Plebanski's book on *Motion and Relativity* published in 1961, the statement occurs: "the radiation can be eliminated by a choice of coordinate systems;" and the authors quote Einstein as having said: "We do not have any satisfactory classical theory of radiation. Ritz understood this fact; and he was an intelligent man."

That was in 1961.

To clarify the doubts that were expressed about the reality of the gravitational waves one had only to ask the following question: Do the equations of motion of a system, when carried out systematically to the requisite order, include terms which may be described as expressing radiation-reaction in the precise sense that these terms contribute to a secular decrease of a quantity, which we may call energy, and which is conserved by the system in the immediately lower order fipproximation to the equations of motion?

A remarkable paper<sup>3</sup> published by Andrzej Trautman in 1958 would have resolved this question unambiguously but for an unfortunate oversight. The oversight, when corrected<sup>4</sup>, confirms the expectation. The problem was in fact fully resolved in 1962 by the fundamental investigations of Bondi<sup>5</sup> and Sachs<sup>6</sup> from a different point of view which I shall not elaborate. After their work, no doubts—that is, no theoretical doubts—were entertained with regard to the reality of the predicted gravitational radiation by systems with time-dependent quadrupole moments.

### Schwarzschild

Finally, I shall consider a third example of how one not only did not ask of general relativity questions which would have clarified its meaning but actually argued against its implications.

The solution of Einstein's equations appropriate to the field outside a central spherical distribution of mass was obtained by Karl Schwarzschild in a paper communicated<sup>7</sup> to the Berlin Academy by Einstein on January 13, 1916, just two months after Einstein himself had published the basic equations of his theory. The circumstances under which Schwarzschild derived his now famous solution are not generally known. I shall digress to tell the story, particularly as 1973 was the 100th anniversary of Karl Schwarzschild's birth.

During the spring and summer of 1915, Karl Schwarzschild was with the German army at the Eastern Front-that was during the First World War. Richard Courant once told me that he had met Karl Schwarzschild proceeding to the Eastern Front while he, as a member of the general staff, was with a party retreating from the same front; and Courant said that he was surprised that someone as distinguished as Karl Schwarzschild would be proceeding towards a front which was considered too dangerous for the general staff. In any event, while at the Eastern Front with a small technical staff, Schwarzschild contracted an infectious disease, and he returned to Germany late in the fall of 1915 very ill. He died on May 11, 1916. As Eddington wrote in a notice published later that year8: "Schwarzschild's end is a sad story of long suffering from a terrible illness contracted in the field borne with great courage and patience.'

But it is not generally known that it was during the period of his last illness that Schwarzschild wrote two of his greatest papers—papers that are great by any standard. One of them<sup>9</sup> was devoted to the theory of the Stark effect and the foundations for the interpretation of band spectra on the Bohr-Sommerfeld

theory, and the other was devoted to obtaining the solution of Einstein's equations appropriate to static systems with spherical symmetry.

Now Schwarzschild's solution for the metric external to a spherical source of total inertial mass M, as he gave it, and as it continues to be written, is

$$\mathrm{d}s^2 = -\left(1 - \frac{2GM}{c^2r}\right)c^2\,\mathrm{d}t^2 + \left(1 - \frac{2GM}{c^2r}\right)^{-1}\,\mathrm{d}r^2 + \\ + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\phi^2)$$

Using this metric, Schwarzschild derived the formulae for the precession of the perihelion of Mercury and for the deflection of light, which Einstein had derived earlier by solving the field equations in an approximation beyond the Newtonian.

It will be observed that Schwarzschild's solution has an apparent singularity at

$$r = R_{\rm S} = 2GM/c^2$$

This is the Schwarzschild radius. Schwarzschild himself was puzzled by this singularity, and he resolved the puzzle for himself in this way.

Since Schwarzschild had considered the metric as describing the field external to a static spherically-symmetric distribution of mass, he investigated in a second paper10, communicated for publication a month later (February 24, 1916), the solution of Einstein's equations appropriate to the equilibrium of a static sphere of constant energy density. He showed that the radius of such a configuration can never be less than  $1.125 R_s$ , and he was satisfied with this result since the singularity of the metric at  $r = R_s$  will not be relevant under the circumstances he had contemplated. It was proved by Birkhoff some years later (1923), however, that a spherically symmetric solution of Einstein's vacuum-equation must necessarily be static, and that Schwarzschild's solution will apply even if the source, spherically symmetric, were not static. Schwarzschild's lower limit,  $1.125 R_s$ , is not applicable under non-static conditions, and we are required to examine more carefully whether the surface has any deeper meaning. I turn to this matter, now.

That there is no real singularity of the geometry of spacetime at  $r = R_s$  was realised very soon. In fact, Eddington showed in 1924 that by writing the Schwarzschild solution in a different coordinate system one can avoid even the appearance of a singularity at  $r = R_s$  along future directed time-like trajectories.

The real significance of the surface  $r = R_s$  becomes clear when one examines the family of 'geodesics in the Schwarzschild metric. The discussion is indeed straightforward, but it was explicitly and fully carried out only in 1958 by C. G. Darwin<sup>11</sup>. In retirement, as he was then, Darwin recalls a paper of his written in 1913 on "Orbits of Electrons" in the field of a nucleus and starts his study with the remark that it might be interesting to examine the analogous problem in the framework of general relativity. Darwin further notes that the analysis could easily have been made forty years earlier. So it might have been, but the problem would have appeared too simple to the 'specialists' that Dyson refers to in the statement I quoted at the outset.

The geodesics in the Schwarzschild metric have been discussed and analysed at great length since Darwin's papers. For the present it is sufficient to draw attention to two particular results. The first is that all photon orbits coming from infinity with an impact parameter less than  $3^{3/2} R_s$  must necesarily enter the Schwarzschild sphere and arrive at r=0, that is, as one says now, these geodesics are future incomplete. The second result is that trajectories, null or time-like, not only must end at r=0, but must do so in a finite proper time as measured by a comoving observer. For these reasons the surface  $r=R_s$  is called an *event horizon*.

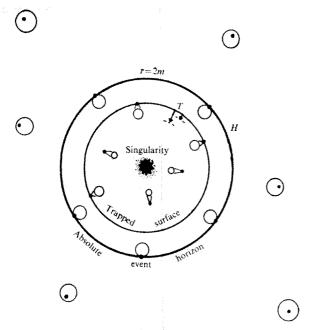

Fig 1 Nature of space-time in the neighbourhood and in the interior of the Schwarzschild radius.

A true picture of the nature of space-time in the neighbourhood and in the interior of the Schwarzschild radius is obtained in the following manner of illustration due to Roger Penrose. In this picture (Fig. 1), the wave fronts of light signals emanating at various points at a slightly later time are shown. At large distances from the event horizon, the points lie at the centres of the respective wave fronts. At smaller distances the wave fronts are displaced by the strong gravitational field present. The wave fronts emanating from points on the event horizon touch the event horizon on the inside and cannot emerge. Inside the event horizon the centre of emission is no longer even inside the wave front; consequently, once inside the Schwarzschild sphere, one cannot communicate with the world outside; and moreover, one would inexorably be propelled towards the centre: not all the King's horses nor all the King's men can prevent it from happening. It should be noted that to deduce all these properties, one has only to draw the light cones at various points—a construction that is entirely elementary.

In essence the significance of the Schwarzschild surface at  $r = R_s$  must have been known to Eddington, certainly by the early 1930s; but nevertheless he would not accept a conclusion which appeared inevitable.

That there is an upper limit to the mass of degenerate stellar configuration had been established<sup>12</sup> by early 1931. Its significance for the final stages of the evolution of stars was fully appreciated at that time as the following extract from what was written at that time shows13:

"The life history of a star of small mass must be essentially different from the life history of a star of large mass. For a star of small mass the natural white-dwarf stage is an initial step towards complete extinction. A star of large mass cannot pass into the white-dwarf stage and one is left speculating on other possibilities."

And Eddington fully realised what this conclusion implied. He stated14:

"The star apparently has to go on radiating and radiating and contracting and contracting until, I suppose, it gets down to a few kilometres radius when gravity becomes strong enough to hold the radiation and the star can at last find peace.'

This remark makes it clear that Eddington realised that the

existence of an upper limit to white-dwarf configurations inevitably requires that in the course of evolution of at least some of the massive stars, black holes—as we now call them must form. But he would not accept the conclusion. For he continued to say:

"I felt driven to the conclusion that this was almost a reducti ad absurdum of the relativistic degeneracy formula. Various accidents may intervene to save the star, but I want more protection than that. I think that there should be a law of nature to prevent the star from behaving in this absurd way."

Indeed, since he considered the conclusion derived from the theory of Fermi degeneracy of electrons, allowing for the effects of special relativity, as leading to a reductio ad absurdum, he modified the relativistic-degeneracy formula so that finite equilibrium states will be possible for all masses.

It is interesting to speculate why Eddington who was one of the earliest and staunchest supporters of general relativity should have found the conclusion that black holes may occur in nature so unacceptable.

### Natural home

The three examples I have described at some length all pre-date the 1960s and are in the context of questions that might have been asked of general relativity, questions whose answers would have contributed to our understanding of general relativity. It will be noticed that the questions one might have asked are precisely questions that have been fully answered during the 1960s in the context of relativistic astrophysics. This is not accidental. In a real sense astronomy is the natural home for general relativity. It has to be so, for the general theory of relativity is a theory of gravity; and in what context, except in the context of astronomy, can one hope to observe manifestations of phenomena derived from strong gravitational fields? In other words, the right physical questions one can ask of general relativity are necessarily in the context of astronomical possibilities.

By saying that astronomy is the natural home for the general theory of relativity, I am envisaging a role for theory in astronomy which is not generally accepted. In my judgment, theory has a double role to play in astronomy: the common one of providing interpretations for observed phenomena; and the uncommon one of providing for astronomy the kind of basis which experiments provide for physics. The latter role is largely unrecognised and largely not practised. But one would certainly recognise this role if one would only stop and realise that unless one can be certain of what one might observe in well defined astronomical contexts, that is, under certain well defined conditions, one could never be sure of any inference that one may draw from observations.

Although I do not wish to go so far, there is an element of truth in an aphorism of Eddington's:

"You cannot believe in astronomical observations before they are confirmed by theory."

### Remnant arcs and marginal basins in the Cainozoic development of the Mediterranean

### M. Boccaletti

Centro di Studio per la Geologia dell'Appennino in rapporto alle Geosinclinali Mediterranee, Via Lamarmora 4

### G. Guazzone

Istituto di Geologia dell'Università, Via Lamarmora 4, Firenze, Italy

Migrations of trench arcs into older marginal basins determined the evolution of the Mediterranean region after the Cretaceous-Eocene closure of the original ocean. Remnant arcs, which now form Corsica, Sardinia and the Balearic Islands separate the Miocene, Pliocene and Recent sea basins. Some remnant arcs such as the Apuseni Mountains separate ensialic basins; others such as the Kabylides, are welded at the fore continental

THE present tectonic structure of the Mediterranean area can only be understood if the geological and structural evolution during the past 100 Myr is considered. Although plate tectonic processes can explain neatly the development of the region there are several problems.

First, the evidence that some basins have opened seems to constrast with a general contraction of this region.

Second, there is a divergence between the continuous alignment of post-Miocene structural units and older discontinuous dispersed elements. That can be explained by assuming a very strong horizontal migration driven by recent arcs, which agrees with the greater length and more pronounced curvatures of the more recent fold belts.

Third, studies of the systematic migration of folded and magmatic arcs in the area suggests that the apparent bipolarity of the main structures is a result of temporally distinct processes1. Coeval symmetric double arc complexes cannot alone be responsible<sup>2</sup>.

• Finally, geophysical and geological data<sup>3-6</sup> suggest that the most recognisable basins (the Mediterranean and surrounding components) spread after a phase of general closure of the ocean. That contradicts the simple idea that the Mediterranean Sea is all that remains of an ocean which has been closing since the Mesozoic<sup>7</sup>.

These problems can be studied using models<sup>8-13</sup> of the development of folded, magmatic arcs and back-arc zones at consuming plate boundaries in the circum-Pacific area.

Geodynamic model for the Mediterranean region

The peculiar character of the structural framework of the Mediterranean area is evidenced by the orientation and winding of the folded arcs, many of which are often connected with others of opposite polarity (Fig. 1). Because the original Cretaceous-Eocene arcs are of opposite polarities, two main zones can be distinguished: the Betic-Alpine zone and the Dinaric-Hellenic zone. The original alignments of these palaeoarcs have been disrupted and in places the arcs have been shifted considerably by successive phases

of contraction during the Neogene. The accompanying shift of former internal zones seems to correspond broadly to reverse polarities of Neogene arc trench systems, and also to a maximum expansion of the marginal basins behind the arcs. The alignment of oceanic scars marked by mafic and ultramafic masses (Fig. 1) shows the same pattern. In spite of their structural relationships with other units the origina location of these ophiolite scars can be identified fairly easily with the two Betic-Alpine and Dinaric-Hellenic belt: which were the true oceanic geosuture. It is debatable whether the two principal alignments of the ophiolitic out crops correspond to one or two oceanic areas14 (tentatively: northernmost Pyreneean-Valaisan-Vardar alignment and Betic-Calabrian-Corsica-Ligurian-Piemon southernmost tais-Serbian-Subpelagonian alignment). The ophiolites which are in any case relicts of a pre-Cretaceous (generally Jurassic) ocean floor indicate a major oceanic closure during the Cretaceous-Eocene (Abbate, E., et al., un published).

The evidence that general contraction of the crust continued after the Eocene suggests that most post-Eocene subduction, and consequently the widest arc migrations must be related to the subduction of the floors of Cretaceous-Eocene marginal basins rather than to the subduction of the original ocean floor. That is how both the western central Mediterranean, and to a lesser degree the Carpathian area, evolved tectonically.

The migration of the Alpine and Hellenic arcs seems however, to have developed with a fairly constant polarity since the Cretaceous. So, if the present structure is considered, at least four main zones can be distinguished (from east to west: Hellenic arcs; Carpathian arcs; Alpine arcs: and Apennine-Tell-Rif arcs).

The first two of these arc systems originated from former Dianaric-Hellenic alignment and the others originated from the former Betic-Alpine alignment.

### Hellenic and Carpathian arcs

Behind the Hellenic trenches there is a series of magmatic arcs which, together with the Aegean Basin constitute a well known, active, marginal basin are trench system. They are recognisable as well conserved relicts of older folded and magmatic arcs and although they all show the same polarity they become progressively older northwards.

In the Hellenic area, fore arc contraction up until the Eocene occurred by the closure of the original oceanic floor. We think that the Balkans, with an opposite Cretaceous-Eocene polarity, can be considered as the coeval

back-arc thrust Belt of the Hellenic arcs18.

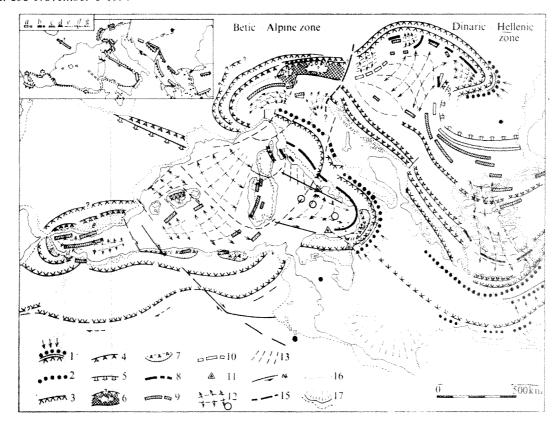

Fig. 1 Geodynamic scheme of the Mediterranean region according to plate tectonic models. 1, Arctrench systems with active subduction; 2, post-Miocene trench alignments; 3, main Miocene and post-Miocene folded arcs; 4, main Cretaceous-Eocene folded arcs; 5, possible Cretaceous-Eocene back-arc thrust belts; 6, Austro-alpine overthrust; 7, microsialic elements of the same Cretaceous-Eocene Betic-Alpine alignment of the Tellian-Apennine arcs. The original 'mother' continent of these sialic fragments, Austro-alpine<sup>6</sup> included, could be the palaeo-African plate (see text): a, Calabrides; b, and c Kabylides; d, Sebtides and Ghomarides: e, Alpujarrides. 8, Post-Tortonian magmatic arcs; 9, Oligo(?)-Miocene magmatic arcs; 10, Cretaceous-Eocene magmatic arcs (relicts); 11, magmatism mainly connected with shear lines; 12, back-arc spread marginal basins with basic magmatism on the floor; 13, pre-spread back-arc distended areas; 14, transform and transcurrent faults; 15, 'Lijubljana-Wien' line separating the Betic-Alpine zone from the Dinaric-Hellenic zone (Cretaceous trench-trench sinistral transform fault and Neogene western limit of the Pannonian and Wien basins); 16, negative gravity anomalies; 17, continental rises and shelves. Inset, correlation and shift of main Mesozoic mafic and ultramafic outcrops: a, alignment of Mesozoic ophiolites considered as elements which have migrated from a southernmost oceanic geosuture; b, ophiolitic elements which have migrated from a northermost ocean geosuture; c, original polarity of the Cretaceous-Eocene geosutures; d, successive polarities during the migration of the reversed arc-trench system; e, shear lines; f, zone (Colantoni, P., et al., unpublished); g, correlation line.

Post-Eocene contraction phases of the arcs developed on the external side, where deep mantle subduction could correspond to the shallow overthrusts of a very thin sialic cover (for instance, the Mediterranean Ridge). Anyway, the type of crust which characterised the floor of the present eastern Mediterranean is still questionable<sup>4,16</sup>.

Instead, the Carpathian area seems to have developed at the expense of the marginal basin behind the Dinarids, with a general inversion of arc polarity occurring after Dinaric welding during the Eocene. This Neogene contraction in its turn determined the spreading of new first order marginal basins (Pannonian Basin) and second order marginal basins (Wien Basin, Transylvanian Basin, and so on). Active subduction is still evidently associated with the extreme eastern Carpathians<sup>17</sup>.

The Apuseni Mountains can also be considered as a remnant arc containing the more internal parts of the inner Dinarids.

### Alpine and Apennine-Tell-Rif arcs

The western Mediterranean was formed from Neogene and Quaternary marginal basins<sup>6,18,19</sup> developed behind the Apennine-Tell-Rif arcs as they migrated southwards and eastwards. The marginal basins, which are of different

stages of maturity are (Fig. 1): the 'Alboran Basin' formed behind the Rif Arc; the first order 'Valencia Basin' formed behind the remnant Baleares Arc; the second order 'Balearic Basin' formed behind the Tell Arc; the first order 'Ligurian Basin' formed behind the remnant Corsica-Sardinia arcs; the second order 'North Tyrrhenian Basin' formed behind the Northern Apennines arc; and the second order 'South Tyrrhenian Basin' formed behind the Calabrian Arc, which is still active.

It is possible to construct a sequence of palinspastic sketch maps to show the possible tectonic evolution of these systems (Fig. 2). There were three phases of Betic-Alpine contraction from the Cretaceous to the Eocene (Fig. 2A, B, and C). The palaeo-European continental margin (of the Atlantic type) includes the sialic fragment of the Balearic Islands in continuity with Iberian sial, and also the Corsica and Sardinia microcontinents (with part of the palaeo-Calabrian sialic substratum) in continuity with the southern French margin. The palaeo-African continental margin (of the Pacific type) is characterised by a festoon of arcs which were migrating northwards together with some detached fragments of African sial. The external ocean floor (Fig. 2A, B) can be correlated with the high pressure and temperature metamorphosed ophiolite suites

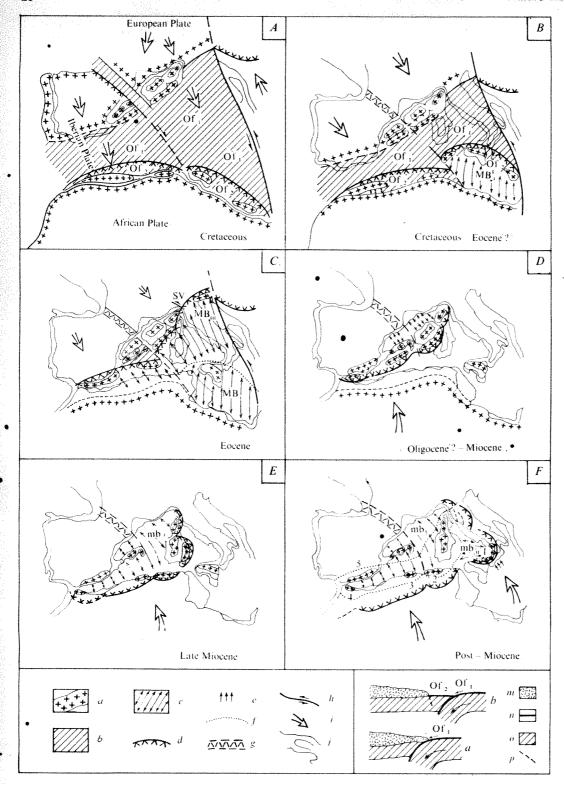

Fig. 2 Hypothetical geodynamic development of the western Mediterranean region. A-C, Creta-ceous-Eocene phases of oceanic contraction with development northward Betic-Alpine belt up to the arc-continent geosuture, with maximum opening of back-arc marginal basins; D-F, Neogene phases of reversed migration of the southward and eastward Rif-Tell-Apennine arc-trench systems up until the present, with closure of former external marginal basins and opening of new back-are basins (the actual western Medibasins, see Continental terranean text). a, Continental crust; b, Mesozoic ocean floor; c, marginal basins; d, folded arcs, showing polarity; e, active subduction areas; f, previous position of palaeoarcs for reference; g, Pyre-naic geosuture; h, trans-form faults; i, possible movements of palaeoplates relative to the deep mantle<sup>31</sup>; j, present geographic contours for reference; MB<sub>I</sub> and MB<sub>II</sub>, first and second order Alpine marginal basins; mb<sub>I</sub> and mb<sub>II</sub>, first and second order Apennine marginal basins. 1, Calabrides; 2 and 3, Kabylides; 4, Sebtides and Ghoma-rides; 5, Alpujarrides. rides; 5, Alpujarrides. Of-1, High pressure and Alpujarrides. temperature metamorphic ophiolites suites belonging to the fore-trench oceanic floor (Schistes Lustrès p.p.); Of-2, low pressure and temperature metamorphic ophiolite suites of the back-trench oceanic floor ('Ligurian' units). SV, Sestri-Voltaggio line; m, continental crust; n, oceanic crust; o, upper mantle; p, pos-sible obduction occurr-

of the Schistes Lustrès complex<sup>20,21</sup>. The internal ocean floor Fig. 2A, B) can be correlated with low pressure and temperature metamorphic ophiolite suites of the Ligurids complex<sup>22</sup>.

The arc-continent collision (Fig. 2C) corresponds to the main geosuture phase recorded by the Betic-Alpine belt. The Pyrenean suture (Fig. 2B) has been indicated tentatively at the Cretaceous-Eocene boundary<sup>23</sup>.

That was followed by an inversion phase (Fig. 2D) when new arcs, with reverse polarity, became detached and started migrating southwards and eastwards. After the Miocene it seems convenient to speak of a pseudo-Pacific and pseudo-Atlantic type for the European and the African continental margins, respectively, because the original Mesozoic ocean had been practically destroyed during the

Cretaceous-Eocene subduction and had been replaced by a system of marginal basins. The continuing migration of the arc trench systems into older Betic-Alpine marginal basins, caused the opening of new marginal basins in the new back-arc area. These Miocene and post-Miocene marginal basins constitute the present western Mediterranean (Fig. 2E and F).

In this context, Corsica, Sardinia and perhaps the Balearic Islands can be considered as interbasins remnant arcs which more or less had their south-eastern sialic margins 'amputated'. These minor fragments were involved in the subsequent arc migration, and in places contained elements of Betic-Alpine scars and covers (for example, the Calabrian Arc).

Thus, the correlation of Calabrides, Kabylides, Sebtides, Ghomarides, Alpujarrides and Malaguides24,26, can be carried up to the Austroalpine overthrust (Fig. 1) and they can all be considered as African elements. In summary, they first welded against the European borders during the Eocene (Fig. 2C) and were then either partially bounced back again on to the late Miocene and post-Miocene African border or are still migrating south-eastwards with the Calabrian Arc (Fig. 2F).

### Unexplained features

Among the many items requiring explanation is the palaeogeography of branches of the Mesozoic ocean. Was, for instance the Pyrenean oceanic channel continuous with the eventual northern Mesozoic oceanic branch? If so, were the opening and closure of the two oceanic branches contemporaneous? Another point needing clarification is the size and width of oceanic branches which have total estimated dimensions, when assembled, of more than 1,000 km<sup>1</sup>

The relicts of the Cretaceous-Eocene magmatic arcs are scarcely recognisable in the western Mediterranean region possibly because of the general inversion of subduction directions and the structural counterthrusts in Oligo(?)-Miocene times.

The external zones of the arcs also pose a problem: both the folding of the outermost covers, and the detachment and shear of the foreland carbonatic platforms27 need to be investigated. For the first point we speculate that the well known gliding tectonics could be related, to a certain degree, to the last vertical effect of the previous active subduction. For the second point, a palinspastic reconstruction is necessary. This must take into account synmigrating sedimentation and a progressive decrease and fragmentation of the original carbonate shelves.

Finally, one of the main geological queries concerns the origin of the Mediterranean evaporites, both buried in the present Mediterranean basins and outcropping along many external arcs28

## New RNA polymerase from *Bacillus subtilis* infected with phage PBS2

### Steve Clark, Richard Losick & Janice Pero

The Biological Laboratories, Harvard University, Cambridge, Massachusetts 02138

Bacillus subtilis infected with bacteriophage PBS2 contains a new rifampicin-resistant RNA polymerase that is apparently composed of four different polypeptides.

THE growth of phage such as T4 (ref. 1), SP01 (ref. 2) and T7 (ref. 3) requires the DNA-dependent RNA polymerase of the host bacteria. Studies with the drug rifampicin, an inhibitor of bacterial RNA polymerases, have indicated that transcription by coliphage T4 and Bacillus subtilis phage SP01 requires the rifampicin-sensitive component of the host RNA polymerase throughout the lytic cycle<sup>1,2</sup>. On the other hand, the growth of coliphage T7 is only sensitive to rifampicin during the first few minutes of infection3 since this phage elaborates a new drugresistant RNA polymerase that directs RNA synthesis late in the lytic cycle<sup>4</sup>. Nevertheless, the host RNA polymerase is initially required for the synthesis of the new T7 enzyme.

PBS2 is a large B. subtilis phage whose DNA genome contains uracil in place of thymine<sup>5</sup>. In contrast to the growth of phage T4, SP01 and T7, growth and transcription by PBS2 are resistant to rifampicin throughout the lytic cycle even if the drug is administered to the host bacteria several minutes before infection<sup>6,7</sup> (T. Fox and S. Clark, unpublished results). A possible explanation for this finding is that when it infects B. subtilis PBS2 injects a new drug-resistant RNA polymerase along with the phage genome. Another possibility is that PBS2 utilises a previously undetected rifampicin-resistant RNA polymerase of the host bacteria. To investigate these possibilities we have searched for a rifampicin-resistant RNA polymerase in extracts of PBS2-infected bacteria.

### Isolation of enzyme

A new RNA polymerase that copies PBS2 DNA in the presence of rifampicin was first detected in crude extracts of PBS2-infected B. subtilis (fraction 1, Table 1). This drug-resistant enzyme was purified partially by ammonium sulphate fractionation (fraction 2) and DEAE-cellulose chromatography (fraction 3). (The enzyme activity at this stage of purification depends completely on added PBS2 DNA.) The enzyme was next separated from B. subtilis RNA polymerase by phosphocellulose chromatography. Host and rifampicin-resistant enzymes were eluted by buffers containing 0.4 M and 0.55 M KCl respectively.

Table 1 Summary of	purifi	ication of	PBS2	RNA po	lymerase
Fraction	$\frac{A_{280}}{A_{260}}$	Total protein	Total activity	Specific activity	Re- covery

gradient enzyme*	******	0.12	54	450	47

B. subtilis 3610 growing at 32° C in 121A medium<sup>8</sup> was infected at a multiplicity of three and collected between 40 and 60 min after infection. The enzyme was purified from 60 g of infected cells. PSB2 RNA polymerase activity was assayed in the presence of 20 μg ml<sup>-1</sup> rifampicin with 4 μg PBS2 DNA as a template. The reaction mixture was as previously described except that the radioactive nucleotide was <sup>3</sup>H-UTP (200 mCi mmol<sup>-1</sup>) and KCl was omitted. One unit enzyme incorporates 1 nmol of <sup>3</sup>H-UMP in 10 min at 37° C. Sonication and high speed centrifugation were as described previously <sup>10</sup>. The enzyme was precipitated from the high speed supernatant fluid by addition of ammonium sulphate to 60% saturation and collected by centrifugation at 100,000g for 1 h. The pellet was resuspended in 100 ml buffer C (0.05 M Tris-HCl, pH 8, 0.1 mM EDTA, 0.1 mM dithiothreitol, 10% v/v glycerol) containing 0.1 M KCl and dialysed against the same buffer. The dialysed enzyme was diluted twofold and applied to a 500 ml DEAE-cellulose column (5.7 × 20 cm) equilibrated with buffer C containing 0.24 M KCl. This fraction was applied to a 15 ml phosphocellulose column (1.9 × 5.1 cm) equilibrated with buffer C containing 0.24 M KCl. This fraction was applied to a 15 ml phosphocellulose column (1.9 × 5.1 cm) equilibrated with buffer C containing 0.24 M KCl. This fraction was applied to a 15 ml phosphocellulose column (1.9 × 5.1 cm) equilibrated with buffer C containing 0.24 M KCl. The polymerase was then eluted with buffer C containing 0.55 M KCl. The phosphocellulose purified enzyme was dialysed against buffer C containing 0.01 M MgCl<sub>2</sub> and 0.1 M KCl and further purified by DEAE-Sephadex chromatography and glycerol gradient centrifugation as described in the legends to Figs. 1 and 2.

\*The fraction 6 activity and recovery have been normalised assuming that all the fraction 5 enzyme had been applied to the glycerol gradient (see legend to Fig. 2).

The latter eluate (fraction 4) was applied to a DEAE-Sephadex column and eluted with a linear gradient of 0.1-0.5 M KCl (Fig. 1). The rifampicin-resistant activity eluted as a single peak at about 0.33 M KCl (fraction 5). Alternate fractions from the DEAE-Sephadex gradients were analysed by sodium dodecyl sulphate (SDS) polyacrylamide slab gel electrophoresis (Fig. 1). Fractions displaying the peak of enzyme activity contained four major polypeptides of 80,000 (I), 76,000 (II), 58,000 (III), and 48,000 (IV) daltons in addition to several other polypeptides in lesser amounts. (Molecular weights were determined by SDS disc gel electrophoresis in phosphate buffer.) As a final purification step, rifampicin-resistant enzyme was subjected to zone centrifugation through a linear gradient of 10-30 % (v/v) glycerol. The enzyme (fraction 6) showed a single peak of activity at 11S, coinciding with a peak of protein and indicating high purity (Fig. 2). SDS polyacrylamide slab gel electrophoresis of the glycerol gradient fractions showed that only the four major polypeptides (I, II, III and IV) of the DEAE-Sephadex-purified

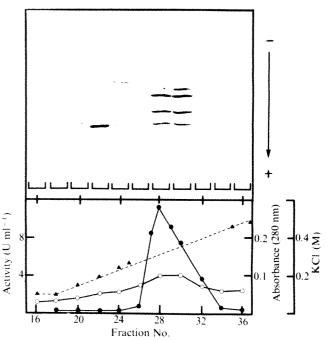

Fig. 1 DEAE-Sephadex column profile. Fraction 4 PBS2 RNA polymerase (6 mg) was applied to a 2.5 ml DEAE-Sephadex column (0.8  $\times$  4.8 cm) equilibrated with buffer C containing 0.1 M KCl and 0.01 M MgCl<sub>2</sub>. The column was washed with 20 ml of the same buffer. The enzyme was then eluted with a linear gradient of 0.1 to 0.5 M KCl in buffer C containing 0.01 M MgCl<sub>2</sub> and 5% (v/v) glycerol. Fractions of 2.4 ml were collected and 25 µl was assayed as described in the legend to Table 1 with 3'H-UTP (100 mCi mmol<sup>-1</sup>) ( $\blacksquare$ ). Alternate fractions were subjected to SDS polyacrylamide gel electrophoresis (8% w/v acrylamide)<sup>11</sup>.  $\bigcirc$ , Absorbance at 280 nm.  $\blacktriangle$ , Molarity of KCl.

enzyme sedimented coincident with the rifampicin-resistant activity. A densitomer scan of a stained SDS disc gel of the glycerol gradient-purified enzyme indicated that the stoichiometry of polypeptides I, II, III and IV was 1.2, 1.3, 1.0 and 0.9 respectively. None of these polypeptides corresponded to the known subunits ( $\beta\beta'\alpha\sigma$ ) of B. subtilis RNA polymerase (Fig. 3).

Glycerol gradient analysis indicated that the rifampicinresistant RNA polymerase is a large enzyme that appears to contain four subunits. Moreover, a molecular weight of 262,000 for a tetrameric enzyme containing all four of the polypeptides is consistent with a sedimentation coefficient of 11S. Proof of this subunit structure, however, will require reconstitution of the enzyme from the separated polypeptides. It cannot be excluded, for example, that the rifampicin-resistant RNA polymerase consists of an aggregate of just one of the four polypeptides and the other three polypeptides are contaminants that happen to copurify with the enzyme even after a greater than 10,000-fold purification (Table 1).

In a preliminary experiment rifampicin-resistant RNA polymerase was also purified partially from PBS2-infected *B. subtilis* by a procedure involving partitioning between phases of polyethylene glycol and dextran followed by agarose gel filtration. Two peaks of rifampicin-resistant RNA polymerase activity eluted from the column: one eluted at a position consistent with the size of the glycerol gradient-purified enzyme, and the other was much smaller and could indicate that other rifampicin-resistant RNA polymerases are associated with PBS2 infection but not detected by the purification procedure of Table 1. Alternatively, the rifampicin-resistant RNA polymerase may dissociate under certain conditions, to yield a subassembly that is catalytically active.

### Comparison of polymerases

Like the RNA polymerase of B. subtilis, the rifampicinresistant enzyme from PBS2-infected bacteria required all four ribonucleoside triphosphates, Mg2+ and a DNA template for optimal activity (Table 2). The rifampicin-resistant RNA polymerase actively copied PBS2 DNA and the synthetic template poly(dA-dT), but was relatively inactive with other DNA templates (Table 2). The ability to copy poly (dA-dT) indicated that the template specificity of the PBS2 RNA polymerase is not limited to uracil-containing DNAs. To investigate the template specificity of this enzyme further, PBS2 and B. subtilis RNA polymerases were assayed with PBS2 DNA and phage Φe DNA at various concentrations of enzyme and template. The rifampicin-resistant enzyme was more than ten times as active with PBS2 DNA than with  $\Phi$ e DNA, while the B. subtilis RNA polymerase was more than ten times as active with Φe DNA than with PBS2 DNA (Fig. 4). As an indication of the fidelity of transcription by the phage polymerase, RNA copied in vitro from PBS2 DNA by the phage enzyme hybridised with high efficiency (45%) to denatured PBS2 DNA but failed to anneal to denatured De DNA (data not shown).

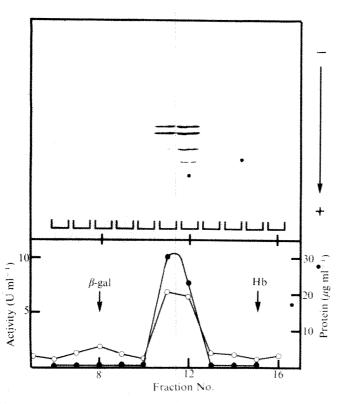

Fig. 2 Zone centrifugation of PBS2 RNA polymerase. Fractions 27 to 31 of the DEAE-Sephadex gradient (12 ml) were pooled and concentrated against Ficoll to a final volume of 2 ml. A sample of 0.5 ml of the concentrated fraction 5 enzyme (0.12 mg) was layered on to a 12 ml linear gradient of 10-30% (v/v) glycerol in buffer C containing 0.1 M KCl and 0.01 M MgCl and centrifuged at 2° C for 18 h at 39,000 r.p.m. in an International SB 283 rotor. Sedimentation standards,  $\beta$  galactosidase and haemoglobin, were sedimented in parallel in a duplicate gradient. Fractions of 0.75 ml were collected and 75  $\mu$ l was assayed as described in the legend to Table 1 with ³H-UTP (100 mCi mmoi ¹) (  $\blacksquare$  ), Each fraction was subjected to SDS polyacrylamide slab gel electrophoresis (8% w/v acrylamide)¹¹¹.  $\bigcirc$ , Protein concentration.

The PBS2 and B. subtilis RNA polymerases differ not only in template specificities but also in their sensitivities to rifampicin, streptolydigin and antiserum against B. subtilis RNA polymerase. The PBS2 enzyme was completely resistant to the drugs and largely resistant to the antiserum, while the B. subtilis enzyme was strongly inhibited by each agent (Table 3).

To determine whether the rifampicin-resistant RNA polymerase is present only after PBS2 infection, we tested for its presence in uninfected bacteria, in PBS2-infected bacteria and in bacteria infected with PBS2 after addition of rifampicin.

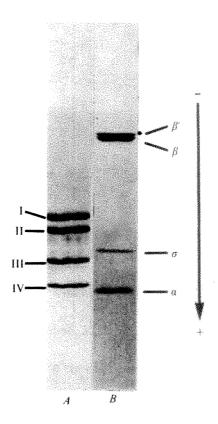

Fig. 3 SDS polyacrylamide slab gel electrophoresis of B. subtilis RNA polymerase and PBS2 RNA polymerase. PBS2 RNA polymerase (A) (3  $\mu$ g of fraction 6 enzyme) and B. subtilis holoenzyme (B) (a mixture of 4  $\mu$ g of fraction 5 holoenzyme and 0.5  $\mu$ g of fraction 7 sigma, prepared as described previously were subjected to SDS polyacrylamide slab gel electrophoresis (8 % w/v acrylamide)<sup>11</sup>

Rifampicin-resistant RNA polymerase activity was assayed at the DEAE-cellulose and phosphocellulose chromatography steps of the procedure of Table 1. Only the infected bacteria contained measurable rifampicin-resistant enzyme activity (Table 4). Thus, the PBS2 RNA polymerase is apparently not present in uninfected B. subtilis but appears after PBS2 infection even in the presence of high concentrations of rifampicin.

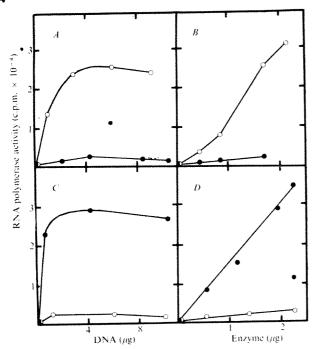

### Implications

The isolation of a new rifampicin-resistant RNA polymerase from PBS2-infected B. subtilis provides a likely explanation for

Table 2 Requirements for PBS2 RNA polymerase activity

	Activity	
	(%)	
Complete system	100	
-ATP	< 1

Assays were carried out as described in the legend for Table 1. The reaction mixture contained 0.9 µg fraction 5 PBS2 RNA polymerase. Except where noted, each assay contained 4 µg PBS2 DNA or 6 µg of the other templates. For the complete system, 100% activity was 17,000 c.p.m.

Template specificity of PBS2 RNA polymerase and B. subtilis RNA polymerase. B. subtilis holoenzyme (1.7 µg purified as described in the legend to Table 3) (A) and fraction 5 PBS2 RNA polymerase (1.9 µg) (C) were assayed as described in the legend to Table 3 with varying amounts of Φe DNA (○) and PBS2 DNA (♠). Various amounts of B, subtilis holoenzyme (B) and PBS2 RNA polymerase (D) were assayed with ♠ DNA (6 µg per assay)(○) and PRS2 DNA (4 µg per assay)(△) Φe DNA (6 μg per assay)(○) and PBS2 DNA (4 μg per assay)(●).

the drug resistance of phage growth during the later stages of the PBS2 lytic cycle. How is this new RNA polymerase initially produced in cells that have been inhibited with rifampicin-before infection? One possibility is that either the PBS2 RNA polymerase, a catalytically active subassembly of that enzyme, or another phage RNA polymerase is encapsulated in the PBS2 virion and injected along with the phage genome at infection. The injected RNA polymerase could then direct the synthesis of additional PBS2 RNA polymerase and other phage proteins independently of the host RNA polymerase. Other possibilities are that the phage injects a protein that confers drug resistance on the host RNA polymerase or that the phage genome is initially transcribed by an unidentified rifampicin-resistant

Table 3 Resistance of PBS2 RNA polymerase to inhibitors of B. subtilis RNA polymerase

Enzyme	Addition	Activity (%)
B. subtilis RNA polymerase	Rifampicin	100
PBS2 RNA polymerase	Streptolydigin Antiserum	8 100
	Rifampicin Streptolydigin Antiserum	100 103 68

B. subtilis RNA polymerase holoenzyme was purified by DEAE-Sephadex chromatography as described previously <sup>10</sup> but omitting DNA cellulose chromatography. B. subtilis RNA polymerase (3.4 µg per assay) and fraction 5 PBS2 RNA polymerase (1.9 µg per assay) were assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend to Table 1 with <sup>3</sup>H-UTP (100 mCl. assayed as described in the legend t assayed as described in the legislation and in the presence of 5 µg rifampicin, 30 µg streptolydigin or 200 µg anti-B, subtilis RNA polymerase antiserum<sup>12</sup>. The template for B. subtilis RNA polymerase was Φe DNA (6 µg) and the template for PBS2 RNA polymerase was PBS2 DNA (4 µg). One hundred per cent activity for *B. subtilis* RNA polymerase and PBS2 RNA polymerase was 58,500 c.p.m. and 35,300 c.p.m. respectively.

RNA polymerase of the host. A recent report indicated that transcription by the phage N4 immediately after infection of E. coli is also resistant to rifampicin<sup>13</sup>. It will be interesting to compare the mechanisms of drug resistant transcription by these unrelated phage.

The purified PBS2 RNA polymerase is complex in structure and, like the RNA polymerase of E. coli and B. subtilis, is apparently composed of multiple subunits. Bacterial RNA polymerases are known to interact with phage-induced polypeptides including the protein products of known regulatory genes<sup>14-18</sup>. The PBS2 genome is unusually large (1.9 imes 10<sup>8</sup> daltons)19 and is undoubtedly transcribed in a defined temporal sequence although the programme of phage transcription has not been investigated. It is tempting to speculate that the PBS2 RNA polymerase, like the multi-subunit RNA polymerases of bacteria, interacts with other phage proteins that regulate the expression of different classes of phage genes during the PBS2 lytic cycle.

Table 4 Appearance of rifampicin-resistant RNA polymerase after infection by PBS2

Extracted from Uninfected B. subtilis	DEAE-cellulose enzyme activity (U mg <sup>-1</sup> ) <0.01	Phosphocellulose enzyme activity (U mg <sup>-1</sup> ) <0.15
PBS2 infected B. subtilis	0.33	22.7
B. subtilis infected by PBS2 in the presence of rifampicin	0.27	18.3

Three cultures of B. subtilis 3610 were grown in medium 121A at 1 nree cultures of B. subtuts 5010 were grown in mediatin 1213 at 32° C to a density of  $2.5 \times 10^8$  cells per ml. One culture (25 l) was infected by PBS2 at a multiplicity of three. A second culture (12 l) was infected similarly by PBS2 5 min after addition of rifampicin (50 µg ml<sup>-1</sup>). Both cultures were collected 45 min after infection. A third uninfected culture (121) was collected at a cell density of 3.5 × 10s per ml. The purification procedure of Table 1 was followed until the phosphocellulose chromatography step. PBS2 RNA polymerase activity was measured as in the legend to Table 1.

We thank A. Price for phage PBS2. This work was supported by a grant from the National Institutes of Health. S. C. is a predoctoral fellow of the US National Science Foundation.

# Enhanced low-energy gamma rays at balloon altitude in the Brazilian magnetic anomaly

The region of the Brazilian geomagnetic anomaly presents an interesting opportunity for the study of precipitation of charged particles of the inner radiation belt into the atmosphere below. Some recent studies based on direct and indirect observations (refs 1–3 and our unpublished work) show that the precipitating flux increases appreciably during the period of a geomagnetic storm. The present note provides another evidence in this direction.

As a part of the continuing cosmic ray programme at INPE, balloons with  $\gamma$ -ray and charged particle detectors were launched on October 7 and 20, 1973. They reached the ceiling altitude of  $\approx 3.5$  mbar and remained there for few hours measuring  $\gamma$ -ray and charged particle fluxes.

The magnetograms obtained at São José dos Campos indicate that on October 20 the balloon was launched during a magnetically disturbed period. It seems that a sudden commencement of small amplitude at about  $0645 \, \text{UT}$  on October 16, 1973, preceded the start of a disturbance in the Earth's magnetic field. It seems that more than one disturbance occurred, so that the period of the balloon flight is a mixture of the main phase and the recovery phase of a magnetic storm. This disturbance continued practically for the whole week. The purpose of this note is to discuss the change in the  $\gamma$ -ray and charged particle fluxes during the disturbed period in relation to those observed during the quiet period in conjunction with relevant geomagnetic and ionosphere observations.

The balloon launchings on both occasions were conducted at São José dos Campos (23°14′S, 45°51′W). On October 7, 1973, the balloon was launched at 0830 UT and it reached a ceiling height of 3.8 mbar but data were obtained for about 30 min only. Even with this short period of observation it is possible to get an idea of the 'normal' level of the γ-ray and charged particle fluxes at the ceiling height. On October 20 the balloon was launched at 0715 UT, attained height of 3.5 mbar at about 0915 UT and telemetered the data obtained for several

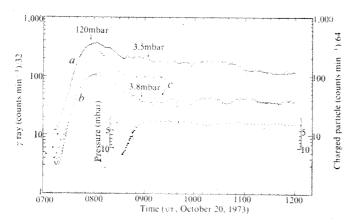

Fig. 1 Count rate as function of time for γ rays (a) and charged particles (b) for the October 20, 1973 flight. Also shown for comparison are the corresponding quantities for the October 7, 1973 flight (c), time shifted so as to coincide with the October 20 curves during the flight ascent. The curve displaying the barometric pressure variation during the October 20, flight is also indicated.

hours. Since the ceiling height of both flights is approximately the same it is meaningful to compare the results and look for effects due to the geomagnetic disturbance.

The detector in both flights consisted of a 4"×4" NaI (T1) scintillator surrounded by a plastic scintillator 1 cm thick. The latter operated in anticoincidence for separating out charged particles. The energy threshold of the detector was such that the minimum energy at the top of the atmosphere of charged particles capable of triggering the detector was 7.0 MeV for electron and 30 MeV for protons. The equivalent area of the NaI (T1) crystal detector is 121.62 cm². The details regarding the calibration and other relevant information can be found in ref. 4.

The curves of the integral count rates as function of time for  $\gamma$  rays and charged particles measured on October 20, 1973 are shown in Fig. 1. The  $\gamma$ -ray count rate is integrated from 0.9 to 18 MeV. A curve for the pressure measurements is also included in Fig. 1. For comparison the curves for  $\gamma$ -ray and charged particle fluxes in the October 7 flight are also shown in Fig. 1, time shifted so as to superimpose the two curves during ascent, without any change in the vertical scale. Starting from the level of maximum count rate at 120 mbar there is a substantial increase in the  $\gamma$ -ray flux. The charged particle flux also shows noticeable enhancement although not as large as in the case of  $\gamma$  rays. At the ceiling height the charged particle seems to have reached almost the normal equilibrium level.

The increased count rate on October 20 can be attributed to the high level of geomagnetic activity prevailing at that time. (The omnidirectional character of the detector and the short time interval between flights exclude the possibility of interpreting the higher  $\gamma$ -ray count rate on October 20 as being due to contribution from any known or unknown celestial source.)

The fact that the increase in  $\gamma$ -ray flux is considerably larger than the charged particle flux may be attributed to the fact, that the  $\gamma$ -ray flux observed is primarily due to bremsstrahlung produced by the downward moving electron flux. Whereas the charged particle detector will register only the flux reaching the ceiling level, the  $\gamma$  ray counts are due to the integrated radiation produced in the layers above the ceiling height. Since the charged particle flux undergoes a decrease with depth, it would be reasonable to expect that the increase in the low energy  $\gamma$ -ray flux should be larger than the directly measured charged particle flux.

To verify this we have calculated from the measured energy loss spectrum in the crystal, the energy spectrum of the incident  $\gamma$ -ray flux (Fig. 2a). For the period 1100-1230 UT (Fig. 2a) the γ-ray count rate was at a lower level, where it stayed for the remainder of the flight. We therefore assume that this period is representative of normal conditions, when no enhanced particle precipitation is taking place. By contrast, the interval 0900-1030 UT (Fig. 2b) covers the period during which the maximum enhanced precipitation is seen to occur. The spectrum for the period 1100-1230 UT is a power law  $\approx E^{-1.1}$  for the entire energy range. For the period 0900-1030 ur the power law is  $\approx E^{-2.2}$  in the range 0.9-2.0 MeV and  $\approx E^{-1.1}$  in the range 7.0-18.0 MeV. In the range 2.0-7.0 MeV, the spectrum is not well represented by a power low in energy. Thus, there seems to be a relatively greater increase in the low energy flux than in the high energy region. Assuming that the increase in the low energy \gamma-ray flux is due to bremsstrahlung from electrons with an energy spectrum given by Pfitzer et al. for

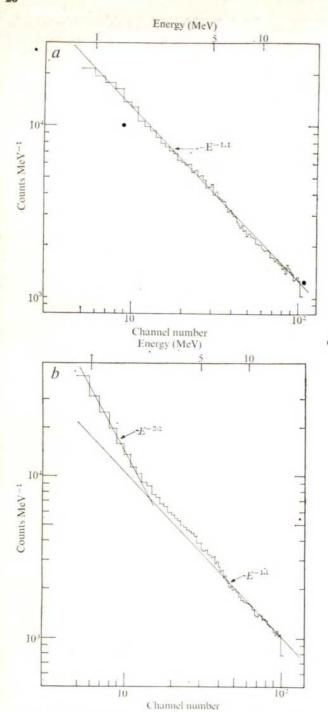

Fig. 2 a, Energy spectrum of the incident γ-ray flux during the period 1100–1230 UT on October 20, 1973. b, Energy spectrum of the incident γ-ray flux during the period 0900–1030 UT on October 20, 1973. 0.164 MeV per channel.

L=1.3, we estimate that these y rays are originating mainly from electrons with energies up to 10 MeV.

Increase in the precipitating particle flux at much lower energies (>40 keV) has also been detected during the period in question by means of change in ionospheric conditions above São José dos Campos. Figure 3a and b show the ionograms taken at 9030 and 1000 UT on October 20 at Cachoeira Paulista located near São José dos Campos. Development of several well stratified ionospheric layers between 100 and 200 km is visible in the ionogram taken at 1000 ur. For comparison we have presented ionograms taken at the same hours on October 13 before the storm (Fig. 3c, d) and on October 26 after the storm (Fig. 3e, f).

Ionograms for October 7, corresponding to the first balloon flight, were not available. The presence of the sporadic E layer at 1000 UT on October 26 introduces some difficulty in interpreting the echoes from the 100-200 km region. But, the nature of the traces obtained at these hours on October 13, and at 0930h on October 26, does suggest that the well defined layer between 100 and 200 km seen on October 20 results from the particle precipitation during the magnetic disturbance on this day.

The association between the increased precipitating flux of high energy particles and the geomagnetic activity has already been noted2. The exact manner in which the geomagnetic field variations produce the increase electron precipitation is not clear. But short-period fluctuations (of the order of few minutes) in the geomagnetic field are believed to provide an effective mechanism (J. M. da C., N. O. T., and D. B. R., unpublished). Records of the total geomagnetic field intensity obtained at São José dos Campos shows that such short period fluctuations are present, and they could thus contribute significantly to the increased precipitation of electrons. An interesting feature

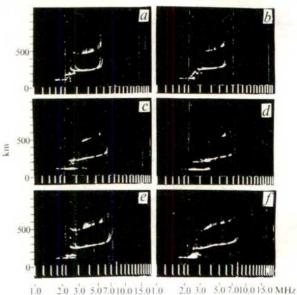

Fig. 3 The ionograms taken over Cachoeira Paulista on October 20. a, at 0930 UT; b, at 1000 UT. Also shown for comparison are the ionograms taken at the same hours on October 13, (c and d) and October 26 (e and f), which may be considered to be normal days. The frequency sweep in the ionograms is from 1 MHz to 20 MHz and the height markings are at 100 km intervals

Frequency

pertaining to the October 7 charged particle measurements is the apparent periodicity of about 30 min seen in the records at the ceiling altitude. There is also some suggestion of a periodicity in the curve of charged particle count rate for the flight of October 20. The corresponding curve for γ-ray flux also shows fluctuations but the periods seem to be shorter. The possible existence of a similar 30 min periodicity has been noted previously1,2 and related to the configuration of the magnetosphere over the anomaly region or to radial diffusion. More observations are needed to establish on more firm grounds the existence of such periodicities before we could attempt any detailed explanation

We thank Dr Fernando de Mendonca for support and Dr Luiz Gylvan Meria, jun., and Mr S. L. Dutra for help.

### Observations of the Orion nebula at 100µ m

WE observed the Orion nebula at coarse spectral resolution during flights on March 13 and 14, 1974, using a cooled grating spectrometer carried on NASA's Lear jet.

The instrument covered the spectral range from 80 to 125 µm at a resolution of 8 µm. It used a Ga: Ge photoconductive detector with an instrinsic long wavelength cutoff at approximately 130 µm, and radiation shortward of 70 µm was blocked by black polyethylene and a Yoshinaga filter. The field of view was roughly 5' square, which is large enough to include most of the brighter portions of the Orion 100 µm source, according to D. A. Harper (unpublished).

To obtain a spectrum the grating was rotated to throw light of different wavelengths on to the detector. At each grating position measurements were made on and off the source, and the difference taken to be the source signal level. Several runs through the spectral bandpass were completed, taking steps of about 5  $\mu$ m, and a raw spectrum was obtained by averaging the values for a given grating position weighted according to the reciprocal of their variances.

Calibrations took two forms. The spectral calibration came from observations of the Moon which had to be taken on separate flights, since the elevation angles accessible to the Lear telescope are restricted and useful observing time is limited to about one hour per flight. But lunar spectra obtained on the mornings of March 11, 12 and 13 and the evening of March 7 are nearly identical. These spectra were used to correct for instrumental profile and atmospheric water vapour absorption, and for this purpose the moon was assumed to radiate as a 390 K blackbody<sup>1</sup>.

The intensity calibration is based on a temperature for Venus (289 ± 20 K) from Armstrong et al.2, and utilises Venus observations from March 11, 12 and 13.

Our Orion nebula spectrum corrected for instrument profile and atmospheric water vapour absorption is shown in Fig. 1 (left hand). Figure 1 (right hand) shows the lunar

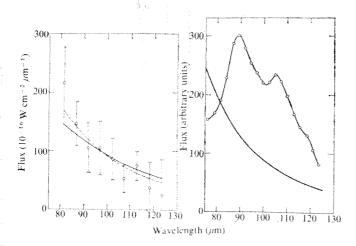

Fig. 1 Right-hand side, Orion nebula spectrum at 8 μm resolution. The blackbody curves are diluted by factors of 83 for 100 K (---) and 2 for 60 K (---). Error bars are one standard deviation. Left-hand side, Calibration spectrum of the Moon ( −○), with superposed 390 K blackbody (—). Errors are too small to plot (<2%).

spectrum obtained on the morning of March 13. The water vapour absorption feature at 100 μm is relatively weak, and this is expected to be the case for all our observations, since they were made from several kilometres above the tropiopause.

Superposed on our Orion data are 60 and 100 K blackbody curves diluted to give the right intensity, since the source does not fill our beam and may not be optically thin. Both curves fit the data, although grain emissivities of the form  $\lambda^{-n}$  give a better fit. Thus the best fits at 60 and 100 K are given by n=1.7 and 0.9 respectively, but in view of the low signal-to-noise ratio the difference from a blackbody is not statistically significant. Pure blackbody curves for temperatures below 40 K do not fit the data well, and the fit improves steadily for higher temperatures. Although our spectrum is somewhat steeper, our results are in good agreement with those of Erickson et al.3. Our flux calibrations also agree with the photometric data of Low and Aumann's and Hoffmann, Frederick and Emery'. The error bars in Fig. •I represent our standard deviation, and are derived from the standard deviations of the individual readings.

Our main conclusion is that our results are consistant with a thermal emission spectrum produced by cool interstellar grains radiating at a wavelength much longer than the grain size. If atomic or molecular lines dominate the 100 µm flux, our spectral resolution is too coarse to detect them, but in any case there would have to be some conspiracy of lines to produce the apparently rather smooth spectrum we detect.

### **Bathonian volcanicity** and North Sea rifting

SEVERAL years ago<sup>1,2</sup> we proposed that the Bathonian and Aptian fuller's earths of southern England, which are montmorillonitic clays, are true bentonites and, therefore, of volcanic origin (see also ref. 3). With the evidence of Bathonian volcanicity associated with rifting in the North Sea, we can now develop the story a stage further.

Two new publications<sup>4,5</sup> outline the pre-Tertiary structure of the North Sea region in terms of a series of troughs separated by upstanding massifs or 'platforms'; we here adopt the more detailed reconstruction of Naylor et al.5 (Fig. 1). They have proposed a model in which thermal expansion of the crust and topmost mantle, perhaps consequent on the rise of a plume, leads to updoming and tensional collapse in the central region. This gives rise to trilete junctions at which three potential spreading ridges diverge. The Forties, Ekofisk and Northern North Sea (or Viking4) troughs form such a rift-rift-rift

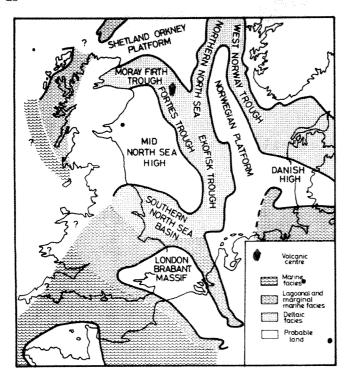

Fig. 1 Structural and palaeogeographic setting of Britain and adjacent areas during the Bathonian.

junction, and it seems to be highly significant that Bathonian volcanicity occurs at least approximately, at this junction4. The implied initiation of a major phase of updoming and rifting at this time can be supported on palaeogeographic grounds.

Considering the Jurassic geology of north-western Europe as a whole, it can be said that the gradual trend, in the early part of the Period, towards increasing marine conditions, with shallow seas progressively deepening and transgressing over the land, was reversed in the Middle Jurassic. All the way across from Britain to northern Germany the sedimentary facies tend to become more regressive from the Toarcian to the Bathonian, before more marine conditions became re-established in the Callovian. The sequence in Yorkshire, for instance, illustrates this well. Marine Lower Toarcian clays and shales pass up into shallower marine sands and ironstones in the Upper Toarcian and Aalenian, and then to mixed, shallow marine, and non-marine deltaic deposits in the Bajocian. The Upper Bajocian and Bathonian are wholly non-marine deltaic, and are replaced once more by marine deposits from the Lower Callovian upwards.

Viewed regionally, the area of greatest regressive tendency within the depositional regime can be identified as the central and northern North Sea (Fig. 1). In Yorkshire, marine influence during the Bajocian diminished northwards<sup>6</sup>, as it did in north-western Germany and southern Scandinavia7. In Andøye, northern Norway, the Middle Jurassic is wholly non-marine and deltaics. The Bathonian of north-eastern Scotland is developed in deltaic facies, with no hint of marine deposits, whereas in western Scotland it is partly deltaic but mainly brackish-lagoonal and marginal marine. Across England and northern France, increasingly marine conditions can be inferred towards the south, and there is an increase in the proportion of calcareous deposits, signifying minimal influx of terrigenous sediment. In the Bathonian, for instance, the deposits are entirely deltaic in Yorkshire, mixed marginal marine and deltaic in the eastern Midlands, marginal marine in the southern Midlands and the Boulonnais and fully marine in Normandy and Dorset. A major source of coarse clastic sediments must be postulated in the North Sea region. Petrological evidence6 indicates this to be, in all probability, reworked late Palaeozoic sandstones, huge volumes of which were uplifted on the Mid-North Sea High and adjacent positive areas. (The London-Brabant Massif does not seem to have been a major sediment source.) The finer sediments were probably derived partly from uplifted Triassic and Liassic rocks in the same areas

Returning to the Bathonian fuller's earth of Somerset, the thickness of 1.5 m for a pure or almost pure montmorillonitic clay seems to be excessive for a single bentonite formed from ast carried some 450 miles from the volcanic centre. The most likely explanation is that a series of major eruptions took place during a restricted part of the Bathonian, at a time datable as Retrocostatum Zone, when normal terrigenous illite-kaolinite clay sedimentation was much reduced in the Bath area. A certain amount of reworking and ponding of ash deposits in smal depressions would have enhanced the thickness locally. Montmorillonite is generally rare in British Jurassic clays and has no been found in beds older than Bathonian. We predict that bentonitic or montmorillonite-rich clays may be found over a wide region in late Bathonian deposits of central and northerr England and Scotland; and they may provide a good stratigraphical marker horizon. On the basis of the bentonite mineralogy and chemistry, and the types of igneous rocks to be expected in early phases of continental rifting, the further prediction can be made that the lavas and/or tuffs will be basic to intermediate and alkaline in composition.

The initial rifting in the North Sea was not followed by seafloor spreading, and therefore, the British Isles did not separate completely from the continent of Europe; only further trough subsidence accompanied by marginal faulting occurred, con stituting what has been termed a 'Failed Arms System5'. This i in contrast to the subsequent Cretaceous rifting to the west and south-west of the British Isles, which also seems to have been associated both with volcanicity, judging from the Aptiar bentonites and other evidence, and upwarping of the continen tal crust, as marked by regional patterns of overstep and sedimentation10.

### Evidence of precursive compression for two deep earthquakes

Dziewonski and Gilbert have claimed that they car detect changes at a seismic source, starting 80 s before the origin time inferred from (impulsive) body wave arriva times. I believe, however, that their conclusion is almos certainly an artefact of their data analysis technique.

Dziewonski and Gilbert used the 'stacking and stripping procedure4-6 to construct Fourier transforms of tim

derivatives of the source time functions. That technique is applicable only at very long periods; as periods become shorter, lateral variations in dispersion become important. Dziewonski and Gilbert computed the transforms of the source rate functions only for periods of more than 78 s. Their procedure is exactly equivalent (if their reconstruction of the source rate transforms is correct) to taking the transforms of the source rate functions over the entire frequency range and then filtering the transforms by setting to zero all Fourier components with periods of less than 78 s, without changing the longer periods.

That type of filtering is 'non-causal.' If a delta function at t=0 is passed through this filter, energy will emerge from the filter at negative times, before the source energy arrives (Fig. 1). Dziewonski and Gilbert's procedure is de-

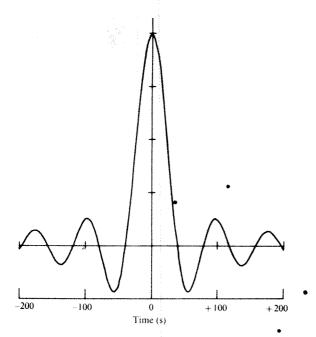

Fig. 1 Impulse response of the filtering procedure used by Dziewonski and Gilbert.

fensible only in cases where almost all of the source rate energy is concentrated in the ultra-low frequency band. But more than 85% of the energy of the (far field) source functions is contained, however, in the short periods, and so they cannot determine an accurate origin time from the free oscillation data set. If the Fourier transforms which they inverted to get their Fig. 2 had included all periods (instead of only the ultra long periods) it is quite likely that the time functions would all have been uniformly zero before the origin time.

The estimate that more than 85% of the spectral energy density was outside the frequency range considered by Dziewonski and Gilbert was derived by combining Aki's statistical scaling rule² with observational data. Aki's rule states that the far field displacement (or source moment rate) spectrum will be flat up to some 'corner frequency', above which amplitude falls proportionally to ω⁻². Because the energy density of the source moment rate is constant below the corner frequency, the total energy in a frequency band from zero to a cutoff below the corner frequency is proportional to ω. The results of Wyss and Molnar³ indicate that 0.1 Hz is a conservative estimate of corner frequency for the deep earthquakes considered by Dziewonski and Gilbert. Thus their cutoff frequency (0.013 Hz) eliminated well over 85% of the signal energy.

The conclusion that the hypocentral region began to undergo compresion 80 s before the observed origin time is, therefore, unjustified.

I thank Freeman Gilbert for comments, and the Advanced Research Projects Agency of the US Department of Defense for financial support.

DRS DZIEWONSKI AND GILBERT REPLY: Although Geller discusses the problem of the rate of release of seismic energy, his criticism of our paper is concerned with our statement that the isotropic part of the moment rate tensor is precursive by 80 s. In this reply, we address ourselves to this precursive behaviour.

If  $g(\omega)$  is the Fourier transform of f(t), then  $g(-\omega)$  is the Fourier transform of f(-t). If  $g(\omega) = g(-\omega)$  then f(t) =f(-t). If  $g(\omega)$  is an even function of frequency then f(t)is an even function of time. If f(t) is an even function of time it is precursive. The experimental evidence for the isotropic part of the moment rate tensor shows its cosine transform, an even function, to be large at low frequencies, and its sine transform, an odd function, to be small everywhere. Consequently, the isotropic part of the moment rate tensor has a Fourier transform that is an even function of frequency, from which follows that it is an even function of time, and, necessarily, precursive. The spectrum of the isotropic part of the moment rate tensor is very small for frequencies above 0.0048 Hz (0.03 s<sup>-1</sup>). The precursor therefore should persist into negative time for about 105 s  $(\pi/0.03 \text{ s}^{-1})$ , which is in accord with our original, conservative estimate of 80 s.

Mr Geller shows a symmetric function of time that has a nearly flat cosine spectrum below 0.01313 Hz (0.0825 s<sup>-1</sup>). It is nothing more than a low-passed delta function. The observed spectrum of the isotropic part of the moment rate tensor decays rapidly with increasing frequency, and is nearly zero above 0.0048 Hz (0.03 s<sup>-1</sup>). Consequently it is not a low-passed delta function and must therefore be precursive.

The only way to invalidate this conclusion is to have the sine transform differ significantly from zero at very low frequencies, below 0.002 Hz (0.0125 s<sup>-1</sup>).

# Correlation of strain and velocity during dilatancy

PRESENT earthquake mechanism models are predicated on the hypothesis of the formation of a dilatant zone in the region of the proposed break and the time history of physical rock properties that are a function of crack porosity. For example, field observations have shown drops in compressional wave velocity in earthquake areas prior to events. The anomaly persists for a time dependent on the source dimensions of the impending shock, and returns to normal prior to the event1-4. Velocity measurements made during laboratory fracture tests have shown a decrease in compressional wave velocity above approximately 80% of the fracture stress<sup>5,6</sup>. The effect is most pronounced normal to the direction of greatest compression. Similarly, as the fracture stress is approached the inelastic volumetric strain is the greatest7, indicating a definite correlation between velocity and inelastic volumetric strain.

Here we correlate spatial variations in compressional velocity with spatial variations in strain over the extended time interval required for the rock to fail under constant stress. A right circular cylinder of Westerly granite was statically loaded in uniaxial compression and velocity observed between the transducer pairs shown in Fig. 1. Coincident illumination and viewing holographic interferometry (refs 8, 9 and N. D. Meyer and H. S., unpublished) enabled us to observe continuously and interpret the entire strain field on the rock specimen.

At the start of the experiment a stress of  $2.28 \times 10^7$  kg m<sup>-2</sup> (2,240 bar) was applied for 24 h; then the load was incremented to be a constant  $2.50 \times 10^7$  kg m<sup>-2</sup> (2,450 bar) and held until failure. Strain (for the last 12 h only) is given in Fig. 1 as radial strain parallel to each of the velocity paths.

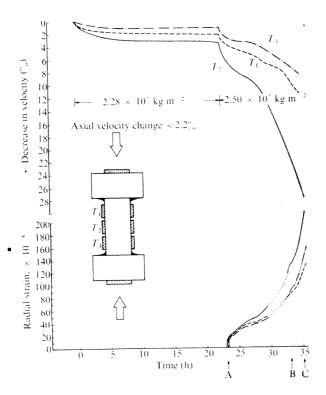

Fig. 1 Decrease in velocity (%) as a function of time over three paths,  $T_1$ ,  $T_2$  and  $T_3$  (see insert), for two creep episodes. The sample failed after 12 h at  $2.50 \times 10^7$  kg m<sup>-2</sup> (2,450 bar). The average radial strain over the same three paths for the second creep event is shown at the bottom of the diagram. The radial strain was calculated from 15 holograms which covered the entire last creep event. The first exposure of each hologram was taken immediately after the second exposure of the preceding one. This yields a complete strain history of the sample.

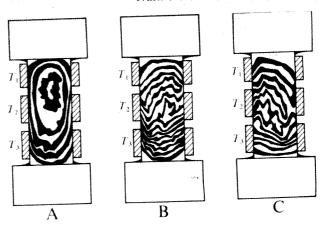

Fig. 2 Tracings of double exposure holograms at times A, B, and C as indicated in Fig. 1. Hologram A shows the effect of an axial stress increase from  $2.28 \times 10^7$  kg m<sup>-2</sup> (2,240 bar) to  $2.50 \times 10^7$  kg m<sup>-2</sup> (2,450 bar), B and C show the effects of creep during 44 min and 13 min intervals con mencing 2.25 h and 0.25 h before failure, respectively.

The total axial strain, measured with a displacement transducer, was nearly linear over the last 12 h and amounted to  $10^{-3}$ . This means that the sample was dilatant during the last episode and the inelastic volumetric strain curve will have the same general shape and characteristics as the radial strain depicted in Fig. 1.

Figure 2 shows three tracings of selected holograms, double exposed at times A, B, and C as shown in Fig. 1. Each hologram contains fringes which can be thought of as 0.3  $\mu$ m contour lines in a topographic map of the surface change of the cylinder. The fringes result from the interference of two slightly different images projected into space.

Hologram A shows the change in surface displacement due to increasing the stress to  $2.50 \times 10^7$  kg m<sup>-2</sup> (2,450 bar). The contours are smooth and form easily identifiable ellipses. The strain is concentrated at the top of the sample and may be characterised as a broad asymmetric bulge along the axis of the sample. The strain field in hologram B taken eight hours after A is much more complex. The fringes are irregular, the strain concentration has shifted toward the bottom of the sample, and the strain ellipse strikes NE. The distortion of fringes is attributed to surface crazing prior to spallation. The contour fringes are much more closely spaced than in A, indicating a larger strain accumulation. The interval between exposures was 44 min. Hologram C was completed 15 min prior to failure; the interval between exposures was 13 min. The greatest strain is still concentrated in the lower half of the sample, and the fringes are distorted, but the strain ellipse now strikes NW. This suggests that the strain field in the sample is not only inhomogeneous but regions of peak strain migrate through the sample. From an examination of all 15 holograms, three such changes in orientation were noted. It seems that two incipient conjugate faults form prior to failure with the strain accumulating on each independently.

The transverse velocity decreased rapidly following the stress increase at approximately 24 h. The slight change in slope at 28 h was then followed by a precipitous plunge toward failure. The radial strain data in Fig. 1 were obtained from holograms along three lines corresponding to the transverse velocity paths. The similarities between the velocity and strain histories are apparent. First, the location of greatest velocity falloff corresponds to the region of largest inelastic strain. Second, there is a definite correlation in the shape of both sets of curves. The transients in all six curves persist for approximately the same period, and the accelerated segments, prior to failure (tertiary creep), all commence at the same time.

So there is a strong correlation between the local inelastic strain and the velocity. The large variations in velocity over

several centimetres distance were unexpected. In addition, the resolution of the holograms presented here shows holographic interferometry contributes significantly in unravelling the local changes in inelastic strain that precede failure.

### Tholeiite, alkali basalt and ascent velocity

ALKALI basalts occur in a great variety of geological environments. It would, therefore, be surprising if only one mechanism were responsible for all occurrences, but we attempt here to explain some features of alkali basalt volcanism which are not readily understood in terms of the deep origin theory.

Engel et al.1 concluded that the great majority of rocks from the ocean floor were tholeiitic basalts, and that the occurrence of oceanic alkali basalts was restricted to the tops of volcanic islands and sea mounts This generalisation is still largely valid, though, apparently, a greater variety of rocks types are found in the ocean basins2,3 than was admitted by Engel et al.1.

The pillow basalts at the top of layer 2 of the oceanic crust are believed to comprise mainly tholeiite, produced at active spreading ridges. The most important parts of many oceanic islands also seem to be tholeiitic; this has been observed for Hawaii<sup>2</sup>, Reunion<sup>4</sup>, and several other islands. Plateau basalts such as the Columbia River Basalts and the Deccan Basalts, are predominantly tholeiitic, as are gabbroic layered intrusions such as Skaergaard and Muskox.

Alkali basalts are frequently produced during the last stage of oceanic volcanism as has been described for Hawaii and Reunion Island, but there are some oceanic volcanic islands, such as the Canary Islands, which seems to be made up mostly of alkali basalts. Alkali basalts also occur at the ocean floor, near ridge axes3 and transform faults7. The Red Sea8,9 and the Afar region10, seem to be underlain by alkali basalt or tholeiite with definite alkaline characteristics. Alkali basalts are typical of the African rift

Alkali basalts are frequently associated with the tholeiitic flood basalts as is the case in Britain and Greenland11. Marginal oceanic basins seem to contain tholeiites which tend to have alkaline characteristics12.

Laboratory experiments<sup>13,17</sup> on the origin of alkali basalts and tholeiites, have been interpreted to indicate that tholeiitic basalts have been formed by a relatively large degree (25%) of partial fusion of a peridotitic parent material at a shallow depth in the upper mantle; and alkali basalts are thought to come from a great depth in the upper mantle. Geochemical arguments based on the contents of trace elements in alkali basalts and their presumed peridotitic parent material, have led to the conclusion that alkali basalts can only be produced by small degrees of partial fusion 18.

We propose an alternative model. Because of the poor thermal conductivity of silicates, vertical movements in the mantle have been considered to be, in general, adiabatic. Thus, the rate at which the temperature changes in a mantle diapir is, to a first approximation, given by the adiabatic gradient: 0.3°-0.5° C km<sup>-1</sup>. If the diapir rises to the surface and is already at a temperature close to its solidus temperature, partial melting can be anticipated, because the solidus temperature of potential upper mantle materials varies with depth by about 4° C km<sup>-1</sup> (ref. 14). If, however, the temperature contrast between the diapir material and the surrounding upper mantle becomes large, and/or when the apward vertical velocity of the moving diapir becomes small, the diapir may cool faster than adiabatic cooling. because heat transport by conduction may then become significant as compared with heat transport by mass transfer.

Numerical calculations 19,20 indicate that at depths of more than 25 km, and velocities of less than 1 cm yr<sup>-1</sup>, the rate of cooling of a massive, upward moving current of silicate crystal mush, becomes greater than the variation of the basalt solidus temperature with depth. When conductive cooling becomes important relative to adiabatic cooling in rising mantle diapirs, the amount of partial fusion of the diapir will diminish; thus, the liquid produced because of . decompression in the diapir will tend to be more alkaline than would be the case for a rapidly rising diapir, in which conductive cooling would be negligible.

In the case of Hawaii, there is evidence that tholeilte is generated at a depth below 60 km (ref. 21) by about 30% partial infusion of a herzolitic upper mantle. Seismic evidence<sup>21</sup> suggests upward lava velocities considerably in excess of 1 cm yr<sup>-1</sup>. If, however, the lava moved upward more slowly, as may occur during the waning stage of volcanic activity, then it may start to precipitate before reaching the surface and will then tend to develop alkaline characteristics which will be further accentuated by contamination with wall rock. Contamination is more serious in slowly moving lavas.

The theory of deep origin for alkali basalts, as applied to Hawaii, suggests that alkali basalt also originates at depth in excess of 60 km, below the oceanic lithosphere, in the asthenosphere or even deeper. The prolonged alkali basaltic activity of islands in the Atlantic, such as the Western Canary Islands, is therefore difficult to understand. Likewise, the apparent total absence of tholeiites on several islands in the Atlantic is not readily explained by the theory of deep origin for alkaline basalts.

Another situation in which the rate of ascent may determine the type of basalt, is the case of very slow seafloor spreading. Basalt erupted at an active spreading centre is thought to be generated by partial melting, as a result of pressure decrease, in upward moving mantle material coming from the low velocity zone 19,20,22. Low spreading velocities imply low rates of ascent underneath the ridge centre. This situation has been modelled quantitatively, and it was found that for vertical velocities of 1-8 cm yr<sup>-1</sup> the composition of ridge basalt does not depend on the rate of ascent But for vertical velocities of less than 1 cm yr<sup>-1</sup> the basalt composition became more alkali rich than tholeiite.

Thus, it can be understood why, in regions characterised by very low plate velocities, alkali basalts or tholeiltes with definite alkaline tendencies are frequently found. An example is the Red Sea8 which has a plate velocity of less than 1 cm yr<sup>-1</sup>. There are alkali basalts at the Goringe Bank in the Atlantic23. This location is situated in the magnetic

quiet zone which itself possibly results from a very slow rate of seafloor spreading24.

### Ubiquitous trisulphur radical ion S<sub>3</sub>

THE colour of blue ultramarine and the deep blue colour of alkali polysulphides in electron pair donor solvents have been attributed to the disulphur radical ion, S<sub>2</sub><sup>-</sup> (ref. 1). That assignment is erroneous and I here establish the correct identity of the species, emphasise the variety of situations in which it is encountered and point out its possible role as an intermediate, in transformations involving elemental sulphur, or sulphide ions.

A blue colour develops when sulphur is heated with water and traces of some basic salt2.3. Blue solutions are also formed by sulphur in alkali halide melts4, in liquid potassium thiocyanate above 300° C (refs 5 and 6), by alkali polysulphides in basic solvents<sup>7-12</sup>, by electrochemical reduction of S<sub>8</sub> in dimethyl sulphoxide13-15 or LiCl-KCl eutectics16,17, and in the electrochemical oxidation of alkali metal polysulphides in eutectics18. The blue species is also present (as a minor component) in

dilute solutions of sulphur in ethylenediamine 19-21 and in the mineral lapis lazuli22,23 and it is formed from proteins containing fully combined cystine, for example, insulin in liquid ammonia<sup>24</sup>, from dimethylamine and elemental sulphur in hexamethylphosphoramide11, and in acetone solutions of sulphur containing potassium hydroxide25

The blue species is characterised by a visible absorption band at 610-620 nm, and it can be attributed to the trisulphur radical anion,  $S_3$  (refs 10, 12, and 15). It is well established that  $S_3$  (in the solid state) has an optical absorption at about 610 nm, which is associated with a Raman band at 534 cm<sup>-1</sup>, whereas S<sub>2</sub><sup>-1</sup> shows a Raman band at 594 cm<sup>-1</sup> associated with an optical absorption band at about 400 nm (refs 26-28). Furthermore, S<sub>a</sub>: exhibits a characteristic infrared band at 580 cm<sup>-1</sup> (refs 10, 11, and 26), (antisymmetric stretching mode), whereas S<sub>2</sub>. is, as expected, infrared inactive. The electron spin resonance (e.s.r.) spectra of  $S_3^{-}$  (ref. 29) and  $S_2^{-}$  (ref. 30) are also well characterised, and the technique has been used to detect S<sub>3</sub>. on the surface of the catalyst when elemental sulphur reacts with partially hydroxylated magnesium oxide at 400° C (ref. 31).

Although the existence of catenated species is a general feature of sulphur chemistry, and probably results from the relatively high  $\sigma$ -bond energy, compared with  $\pi$ -bond energy, for sulphur<sup>20</sup>, the formation of  $S_3^{-}$  in preference to other sulphur radical ions is not readily explained. Like other 19e triatomic molecules for example,  $Q_3^{-1}$  and  $ClO_2$  (refs 32, 33)  $S_3^{-1}$ will have C<sub>2v</sub> symmetry with SSS < 120°. The odd electron will occupy a molecular orbital which is S-S antibonding, but bonding with respect to terminal sulphur atoms<sup>34</sup>. The possibility of S · · · S interactions between terminal sulphur atoms must, therefore, be considered. For the  $S_3^{2-}$  ion, of known structure<sup>1</sup>, the separation would be 3.37 Å. According to the Walsh rules for triatomic molecules<sup>34</sup>, the SSS angle would increase slightly for  $S_3^-$  whereas the S-S distance should decrease compared with  $S_3^{2-}$ , so that the  $S \cdots S$  separation in  $S_3$  can be expected to be similar to that in  $S_3^2$ . Although this value is lower than the sum of the Van der Waal's ratio for sulphur (3.70 Å), it is considerably larger than the S-S intraring interactions in  $S_8^{2+}$  [ $d(S_3-S_7)=2.86$  Å]<sup>35</sup> and about the same as the intraring distance in  $S_8 [d(S_1 - S_3) = 3.33 \text{ Å}]^{36}$ which is not regarded as implying a significant interaction<sup>37</sup>. It is noteworthy, however, that the dithionite ion, S<sub>2</sub>O<sub>4</sub><sup>2</sup>, with an unusually long S-S distance (2.39 Å)38 dissociates in oxygenfree aqueous solution to give the SO<sub>2</sub> radical ion<sup>39</sup>, isoelectronic with  $S_3^{\pm}$ .

The probable significance of the S<sub>3</sub><sup>-</sup> radical ion (and other sulphur radical anions) in a wide variety of situations should be recognised. For example, the formation of S<sub>3</sub>. in superheated water must be considered in a discussion of sulphur transformations which occur in geothermal springs40. The discovery that sulphur radical ions are the electroactive species in the electrochemical oxidation of polysulphides is significant to battery technology, particularly for the application of Na/S<sup>0</sup> or Li/S<sup>0</sup> couples in secondary battery systems18. The formation of sulphur radical ions on the catalyst surface should be taken into account in any discussion of the mechanism of desulphurisation reactions and the reduction of SO<sub>2</sub> over metal oxides<sup>31</sup>. The well known Willgerodt-Kindler reaction provides an example of the catalytic effect of amines on the reactions of elemental sulphur<sup>41</sup> which undoubtedly involves the formation of polysulphides42, and thus, sulphur radical ions15,43.

The common feature of the wide variety of conditions in which the  $S_3^{-1}$  ion is formed is the existence of conditions in which polysulphide ions,  $S_x^2$ , are either present or can be formed easily. The trisulphur radical ion can then be produced from polysulphides either through dissociation (x = 6) or by disproportionation (2 < x < 6). As electrochemical studies<sup>13-18</sup> have shown that the reduction  $S^0 \rightarrow S^{2-}$ , or the oxidation  $S^2 \longrightarrow S^0$ , is not a single step process but occurs through polysulphide ions, the intermediacy of sulphur radical anions, for example, S<sub>3</sub><sup>-</sup> in, for instance, the biological oxidation of sulphide, is a real possibility44. Indeed, sulphur radical ions

have been invoked to explain the oxidation, by aqueous polysulphide solutions, of aryl methyl compounds to the corresponding carboxylic acids45.

## Laser-induced orientation in macromolecular suspensions

We report here the first realisation of laser-induced changes in the orientation of macromolecules and particles in a liquid medium. We give preliminary data on the induced birefringence of two, very dilute, macromolecular suspensions; and we show that the

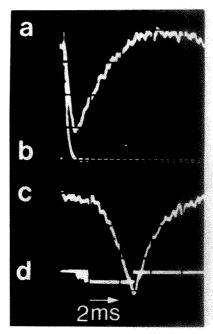

Fig. 1 Birefringence induced in Bentonite sols, at a wavelength of 488 nm. a, Laser-induced birefringence response; b, YAG laser  $(\lambda=1.06~\mu m)$  'fixed Q' pulse of approximately 8 kW maximum power; c, electrically induced birefringence response; d, a direct current electric pulse, of amplitude 31 V cm<sup>-1</sup>. Time scale, 2 ms per division; a linear detection system<sup>11</sup> was used. For b and d the same incident light intensity was used; the amplitudes of the responses are directly comparable and actually represent decreases in intensity and, thus, a negative birefringence. The sol concentration was  $1.3 \times 10^{-3}$  g ml<sup>-1</sup>.

effects accompany particle orientation rather than local heating or refractive index changes, and that they therefore indicate the foundation of a new method for characterising macromolecules.

Many molecules and particles have anisotropic optical properties. When suspended in a liquid they adopt random orientations and the overall medium is optically isotropic, until some external force field-electric, magnetic, acoustic, and so on-is applied to the suspension. Then, the anisotropic properties of the individual particles become partially impressed on the bulk medium, as the suspended particles become aligned.

Changes in the optical properties (scattered intensity), birefringence<sup>2</sup>, dichroism<sup>2</sup>, optical activity<sup>3</sup>) when pulsed electric fields are applied, have been studied often in macromolecular suspensions. The pulsed method enables molecular relaxations to be studied, whilst electric fields lead to information on the permanent dipole moments and electric polarisabilities of the suspended particles. These 'electro-optical' methods have proved particularly valuable in the study of macromolecules, because of their relatively large permanent and induced dipole moments.

It has been predicted4 and shown experimentally8 that the electric field associated with a suitably highly powered pulsed laser could provide the force field in the case of simple liquids. Similar effects have been anticipated<sup>6</sup>, but not until now realised experimentally for suspensions of macromolecules.

We assembled a conventional birefringence apparatus, with an Argon Ion, low power, continuous working laser which provided the probe light beam at a wavelength, \(\lambda\), of 488 nm. The 'orienting' beam was obtained from a Nda+ YAG laser working at a wavelength of 1.06 µm. At optical frequencies, only the electronic contributions to the electrical polarisability are effective, so that a high field is required before a suitable dipole moment can be induced in the molecules. Relatively long orientation times, from 10 µs to 1 ms, are required for the rotation of macromolecules?. To satisfy both of these requirements, the YAG laser was operated in a 'fixed Q' manner, in which the gain of the cavity was fixed and the laser was driven at a high power for a short, prefixed time; in this case approximately

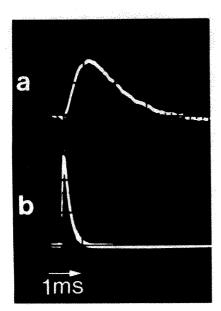

Fig. 2 Laser-induced birefringence of a solution of TRV at a wavelength of 488 nm. a, Birefringence response from TRV. Time scale, 1 ms per division. The response is an increase in light level and, therefore, a positive birefringence effect. TRV of  $3 \times 10^{-3}$  $ml^{-1}$  was studied in M/60 Sorinsens phosphate buffer at pH = 7.0. b, YAG laser 'fixed Q' pulse of approximately 8 kW maximum power.

200 us. Conventional Q switching produced pulses which were much too fast. The power of the 'fixed Q' beam was monitored through a calibrated photodiode and an approximate equivalent field strength, E, was calculated using the Poynting vector equations8. Precise values for E were not obtained, because of the complex shape of the pulse with time. It was important to operate the YAG laser in the single transverse mode, for only then was the electric vector undirectional throughout the beam cross-section. The beam was unfocused and polarised at 45° to the azimuth of the initial polariser of the birefringence optics. Using suitable dielectric coated mirrors, which transmitted the probe blue light but totally reflected the YAG infrared radiation, the orienting beam was made to travel the length of the sample cell together with the probe beam, thereby allowing a large optical cell length.

Aqueous suspensions of Wyoming sodium bentonite, a disklike clay mineral9, and a solution of tobacco rattle virus (TRV), a rod-like virus<sup>10</sup>, were studied. Figures 1a and 2a are typical of the transient birefringence traces observed. In each case the applied laser pulse is shown (Figs 1b and 2b). In order to verify that these effects arose from particle orientation, two further experiments were performed. In the case of the bentonite sol, a pulsed d.c. electric field (Fig. 1d), of suitable amplitude and duration, was applied after the laser beam. The field strength was chosen to give a similar birefringence response

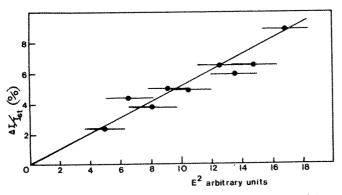

Fig. 3 Change of maximum birefringence with the square of the effective field strength, E, of the YAG laser beam. With linear detection, the light intensity change,  $\Delta I$ , is directly proportional to the birefringence, and Ist represents the residual transmitted intensity. Data for TRV.

(Fig. 1c) to that induced by the laser beam; the transient decay from both the electrically and the laser-induced effects have the same time constant, within experimental uncertainty. When interpreted as a molecular relaxation time,  $\boldsymbol{\tau},$  in the conventional manner for electric birefringence data, a value of  $\tau = 1.9$  $(\pm 0.2)$  ms was obtained. That is typical of the rotational relaxation time of that material12. With TRV, the laser-induced birefringence led to a value of  $\tau$ =1.0 (±0.1) ms, which also agrees with the value reported elsewhere13.

Rotational theory also predicts that2 the birefringence increases as the square of the electric field. Measurements were made as a function of the laser power and are presented in Fig. 3 in terms of the strength of the equivalent electric field; Fig. 3 shows the predicted quadratic dependence on E.

Future experiments will be made to quantify accurately the amplitude of the induced effects so that the electronic contribution to the polarisability can be isolated. Apart from that, and the close association with nonlinear optical effects, particle sizes can also be evaluated14 from  $\tau$ . We conclude, therefore, that these preliminary studies could lead both to a series of experiments which characterise macromolecules, and to a greater understanding of their electrical and optical properties.

## Total reflection as derived from statistical scattering and coherent scattering theories

In the past ten years there has been much investigation of the interesting phenomenon of microscopic bubbles in liquids, particularly liquid helium, which are maintained by the presence of a light particle, such as an electron1 or positron2. In both cases, with liquid helium the bubble is believed to arise from an effective repulsive potential between bulk liquid and the light particle. Coopersmith<sup>3</sup> derived an expression for this effective potential by calculating the free energy of a light particle moving in a space having randomly distributed hard spheres.

The hard spheres move as in a classical ideal gas and statistical equilibrium between light particle and gas is assumed. Only s-wave scattering was considered. The mean free energy of the light particle is found to have a minimum energy which is due to space-limitation of its motion. The interaction free energy was shown rigorously to be

due to single scattering, all higher order multiple scattering effects being zero. In equation (1) n is the density of scattering centres,  $a_s$  the scattering length and m the light particle mass. Thus a particle of mass m striking the surface of a liquid having n molecules per unit volume from outside would require a kinetic energy at least  $k^2h^2/2m=E_F$  in order not to be totally reflected from the liquid surface. Therefore, the critical wave number for total reflection at normal incidence is given by

$$k^2 = 4\pi n a_s \tag{2}$$

Eighteen years earlier, Goldberger and Seitz<sup>4</sup> investigated coherent scattering from randomly distributed scattering centres, and produced results which have, for example, been applied to neutron refraction at liquid surfaces. According to their theory a particle of mass m will be totally externally reflected when normally incident upon a liquid surface unless

$$k^2 \geqslant 2n(\pi\sigma_s)^{1/2} \tag{3}$$

which agrees with equation (2) if we put  $\sigma_s = 4\pi a_s^2$  and take the positive square root, indicating repulsion.

So these two strikingly different approaches yield the same result in the low energy limit, for s-wave scattering.

## Measurements of K, Rb, U, Sr and Pb in diamonds containing inclusions

KNOWLEDGE of the Pb and Sr isotopic compositions of syngenetic inclusions in diamonds is important for several reasons. As diamonds probably crystallised at depths of more than 100 km, the isotopic data may provide constraints on the mode of the geochemical evolution of the Earth. It may also be possible to test assumed U/Pb ratios  $(U/Pb=\mu)$  for the mantle and to estimate the age of particular diamonds. Diamonds are particularly appropriate for these studies because, in contrast to kimberlites and their associated nodules, any contamination by crustal material can be overcome by washing in acid.

Here we report preliminary measurements of the K, Rb, Sr, U and Pb concentrations in diamonds. As far as we know the only other reported measurements are by Fesq et al.1 who used instrumental neutron activation analysis to determine the concentrations of Sr, Rb and K. They found that these elements are far more abundant in diamonds with visible inclusions than in those apparently free of inclusions.

We investigated two batches of diamonds from the Premier Mine, South Africa, one containing green (mainly diopside) and the other black (mainly sulphide) inclusions. The 'green' diamonds (22 stones, weighing 0.2674 g) were analysed for Sr, Rb and K, and the 'black' diamonds (27 stones, weighing 0.3188 g) for Pb and U. The diamonds were small, 1-2 mm in size (in general, inclusions are of roughly constant size, so for a given weight of diamonds the percentage occupied by the inclusion is highest in small stones). The diamonds were colourless or brown, of good crystal morphology and free from surface fractures.

Diopside is a fairly common inclusion in Premier Mine diamonds, occurring as pale green euhedral or anhedral crystals. The diopsides chosen were free from associated black material<sup>2</sup> although in some cases internal fractures were present. The sulphide occurrences in diamond are more varied2, and sulphides occurring in internal rosette fractures associated with colourless inclusions, and as discrete sulphide inclusions were chosep. The sulphides probably consist mainly of pyrrhotite2, but the chemistry was not determined. They were distinguished from graphite by colour and lustre3. The percentage by weight that the inclusions occupied within both batches was roughly estimated as 0.1%.

The Premier pipe is older than 1,115±15 Myr and younger than  $1,954 \pm 30$  Myr (refs 4 and 5). It contains at least four distinct intrusions of kimberlite with ages that may range from 1,200-1,400 Myr, but it could not be ascertained to which type our diamonds belonged. The best dated type of kimberlite (Type 1) has a Rb/Sr age of 1,250 ± 20 Myr (H. L. A. unpublished), so we assumed that age in our work, but the assumption of any age in the range indicated would not affect significantly our tentative conclusions.

For each experiment we used only 10 g of reagent prepared by triple distillation in quartz under sub-boiling point conditions (in the case of H<sub>2</sub>O and HCl); HF and HNO<sub>3</sub> were prepared as in ref. 6.

The diamonds were cleaned by prolonged and repeated heating and ultrasonic agitation in HF, HClO, and water, and then burnt over a period of about 15 min in a clean, covered quartz crucible at ~ 850°C, in a flow of highpurity filtered oxygen. A preliminary experiment using a platinum crucible gave a Pb blank much higher than the quartz; but even the quartz (or possibly the oxygen) still constitutes a serious source of Pb contamination. The crucible, about 15 cm long, had a water-cooled ring near the top to condense volatilised molecules.

The residue was transferred to a teflon autoclave using dilute acid. After HF was added it was heated at 200° C for 6 h. After evaporation the residue dissolved readily in dilute HCl. This solution was then aliquoted for three separate mass spectrometer analyses: isotopic composition (of Sr and Pb); concentration of K, Rb (jointly) and U; and concentration of Sr and Pb.

Concentrations were determined by isotope dilution. Isotopic tracers of high purity (>99%) were used in all

cases except U, and the sensitivity was accordingly good for all elements except U. The accuracy of the concentration data is limited in all cases (again except U) by the blank levels and not by the precision of the mass spectrometer measurements. Potassium, rubidium and lead were run on single filaments by the silica-gel method, and Sr and U were run on double filaments. The decision to make no chemical separations of the elements under consideration had deleterious effects in both the Sr and Pb isotopic composition analyses. With Sr, Rb interference "Rb/8"Sr~2%) was a problem, but correction using \*\*Rb/\*\*Rb=2.600 was considered reliable as no samples enriched in 87Rb have even been measured on the mass spectrometer in question. With Pb, although test runs with pure, 50 ng, Pb samples gave satisfactory ion beams, the diamond sample yielded only a small beam (204Pb~1-3 mV), and this severely limited the precision.

Table 1 shows the results obtained. The blanks of Sr, K and Rb (both on the reagents and on the full procedure) are of an acceptably low level, but the blanks of U and Pb amounted to 25% and 32% of the sample, respectively. The U tracer used is not sufficiently sensitive for such low level work, and the blank levels may well have been overestimated. Only in the case of Pb is the full procedure blank significantly greater than the reagent blank. The most significant result is that ~ 30 and 60 ng of Pb and Sr,

respectively, are contained in the relatively modest quantities of diamonds used. On the evidence of Fesq et al.1 and our own unreported data from a preliminary experiment on a batch of diamonds with only graphite inclusions, we believe that this Pb and Sr is contained in the inclusions; using the very rough abundance estimates of the inclusions, the concentrations are ~ 100 p.p.m. of Pb in the sulphides and  $\sim 200$  p.p.m. of Sr in the diopsides. But even if the Pb and Sr is contained in the diamond structure rather than in the inclusions, our conclusions relating to the isotopic data will not be affected. The K/Rb ratio of the diopside inclusions is ~ 200, a similar value to that obtained for periodotite nodules and their constituent diopsides8.

The Pb and Sr isotopic ratios were corrected in several ways. The \*7Sr/\*6Sr ratio was normalised to a \*\*Sr/\*6Sr ratio of 8.375; if the 87Sr/86Sr ratio of the contamination Sr was 0.7090, the blank correction is negligible; correction for the radiogenic component was made on the basis of the measured Rb/Sr ratio and an age of 1,250 Myr. The 207Pb/ <sup>204</sup>Pb and <sup>206</sup>Pb/<sup>204</sup>Pb ratios were arbitrarily corrected for fractionation by comparing measured and accepted values on the NBS 981 standard Pb. Correction for the radiogenic Pb was made using the measured U/Pb ratio, and because of the large uncertainty in this ratio, the error on the isotopic ratios has been increased arbitrarily. The influence of the isotopic composition of the contaminating Pb is in

Table 2 Rb, Sr and 87Sr/88Sr values for Premier carbonatites

	1 able 2	Ro, Si anu	31/ 31 value	3 IOI I I WING
Sample	Rb (p.p.m.)	Sr (p.p.m.)	<sup>87</sup> Sr/ <sup>86</sup> Sr	Remarks
PC/B PC/2 PC/3	0.32 1.48 0.85	1,042 838 1,579	0.7025 0.7032 0.7044	High Mg-brucite Si-rich kimberlitic carbonatite A complex rock, predominantly calcite

 $<sup>^{87}</sup>$ Sr/ $^{88}$ Sr corrected to  $^{88}$ Sr/ $^{86}$ Sr = 8.375; accuracy in  $^{87}$ Sr/ $^{86}$ Sr estimated as  $\pm$  0.0003. Using an age of 1,250 Myr the correction for radiogenic Sr is negligible. Three distinct types of carbonatite were sampled, and all samples were petrographically assessed to be fresh. Sample PC/3 contains, however, two generations of calcite and some of the calcite may be crust-derived; that would account for the higher 87Sr/86Sr ratio and this result is rejected.

Using measured blank lead isotopic composition 206/204 = 18.08; 207/204 = 15.68; 208/204 = 38.77. ¶ Using age of Premier pipe of 1,250 Myr; error for Pb ratios arbitrarily increased to take account of uncertainty in U/Pb ratio;  $\lambda^{Rb} = 1.39 \times 10^{-11} \text{ yr}^{-1}$ .

this case large, and so an approximate measurement of this parameter was made by combining the Pb ( $\sim 25$  ng) from two blank runs.

The diagram shows the corrected and uncorrected Pb isotopic ratios in relation to Pb growth curves. In view of the limited nature of the data these results must be treated with caution, but it seems that the  $\mu$  value for the source region of these diamonds is close to 9.0 and that if a single-stage model is assumed, the age is close to 1,500 Myr. Whether this age refers to the time of pipe formation (assuming that isotopic equilibrium was maintained between Pb in possibly older diamonds and in the surrounding mantle until pipe formation), or to the time of diamond formation itself, is unknown. Further data are needed; a prime objective of such work would be to detect possible mantle depletion in the lithophile elements, as reflected by changing  $\mu$  values with time.

A \*7Sr/\*\*Sr ratio for carbonatite from Premier, of  $0.7028 \pm 0.0003$  has been reported, and the results of three further measurements are listed in Table 2. The kimberlite found at Premier is considered as too altered to warrant analysis (see ref. 10), but the fresher carbonatites, if derived from an original kimberlite magma rich in carbonates, should have the same \*7Sr/\*6Sr ratio as the original kimberlite. The fact that the corrected 87Sr/86Sr ratio for Premier diamonds (0.7028 ± 0.0006) is almost identical with the results listed here for carbonatites from the same source, suggests a genetic relationship between diamonds and the original kimberlite magma. The observed \*7Sr/\*\*Sr ratio is lower than the main trend for basic rocks from southern Africa5; layering of the mantle is implied, with the deep-seated source region of the diamonds characterised by low \*7Sr/\*\*Sr ratios.

We particularly thank Professor W. F. Slawson, who suggested this project, the personnel of de Beers Diamond Sorting Office, Kimberley, for their cooperation; the South African Atomic Energy Board for the use of their mass spectrometer; and I. J. D. van der Westhuizen for assistance with the measurements. Dr R. Danchin provided the carbonatite samples and their petrographic assessment. This work was supported financially by the Anglo-American Corporation.

### Skull of Palaechthon nacimienti

Species in or near the ancestry of living primates first appear in the late Cretaceous and early Palaeocene of North America. Subsequent adaptive radiation of the Purgatorius-like ancestral stock produced the plesiadapoid families (Plesiadapidae, Carpolestidae, Paromomyidae) of the middle and late Palaeocene. Specialised members of all three families survived into the early Eocene, the paromomyid genus Phenacolemur persisting into the late Eocene. Most of the plesiadapoid species are known only from incomplete dentitions. In 1948, a crushed but nearly complete skull of a paromomyid was recovered from strata of middle Palaeocene age in the Kutz Canyon area of the San Juan Basin, New Mexico. The specimen has been described by Wilson and Szalay1, who assign it to a new species (P. nacimienti) of the genus Palaechthon, known also from the mid-Palaeocene of Montana and Wyoming. The loss of the upper and lower first premolars excludes P. nacimienti from the ancestry of some of the Eocene prosimian lineages. Nevertheless, its persistently primitive molar morphology suggests that it may more closely resemble the last common ancestor of the plesiadapoids and the Eocene primates of modern aspect than do other plesiadapoids for which cranial remains are known. Skulls or partial skulls are known for dentally more specialised genera of each plesiadapoid family: Plesiadapis (Plesiadapidae), Carpolestes (Carpolestidae), and Phenacolemur (Paromomyidae).) We present here a reconstruction of the skull of P. nacimienti, together with some preliminary functional interpretations of its cranial and dental anatomy.

The skull is unevenly crushed in the dorsoventral plane and lacks the zygomata and the anterior extremity of the rostrum. Its caudal end is missing, including the greater portion of the petrosals and basioccipital, the occipital condyles and foramen magnum, and the corresponding portions of the skull roof. The basicranium is badly fragmented, and foramina cannot be identified with certainty. The ear region is represented only by dubious fragments of the anterior tip of the petrosal; the bulla is completely lost. (The original description of this speciment stated that "... there are signs that a sizable bulla was present," and that "the pterygoid crests are only 0.7 mm apart". The authors may have mistaken fragments of the widely-divergent pterygoid laminae for fragments of the bullae.) Relative brain size cannot be estimated from the preserved material.

Each of us attempted an independent reconstruction of the skull. The results differed in only a few details, which were resolved in preparing Fig. 1. Linear measurements of the skull

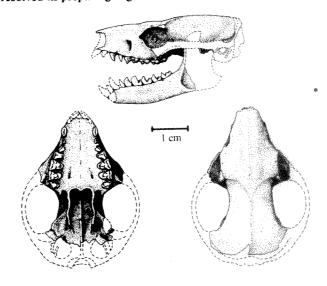

Fig. 1 Ventral, lateral, and dorsal views of the skull of *Palaechthon nacimienti*, based principally on Univ. Kansas Nat. Hist. Mus. No. 9557 and No. 9559. Specimen UKMNH No. 7903, which was originally included in the hypodigm of *P. nacimienti*, represents a new species and accordingly was omitted from consideration here.

and teeth were compared with similar data for extant prosimians, tree shrews, elephant shrews, dermopterans, squirrels, didelphids and phalangerids, as an aid in assessing the adaptive significance of the fossil's morphology.

The cheek teeth of *Palaechthon* show a constellation of features similar to that seen in the extant insectivorous prosimians *Loris*, *Arctocebus*, *Tarsius*, *Galago demidovii* and *Galago senegalensis*. The molars are relatively large and heavily worn. The lower molar crowns of *Palaechthon* are relatively high, and exhibit pronounced concavely-curved leading edges of wear surfaces 1-4. (These and related terms used here are defined in ref. 2.) In mastication, these edges were moved dorsally and anteromedially past matching pairs of reciprocally-curved upper molar blades. The leading edges of upper and lower wear surfaces 5 and 6 are also long. These features are correlated with shearing functions and resistance to wear, and are reduced in more frugivorous extant prosimians<sup>3</sup>.

In Palaechthon, the origin of the anterior temporalis muscle extends forward to a point above the posterior upper molar. The faint temporal lines converge to form a midsagittal line which extends over approximately the posterior 70% of the temporal fossa. The linea obliqua of the mandible, which strengthens the coronoid process against the pull of the temporalis and provides an insertion for the anterior and zygomatic parts of that muscle, is robust and in high relief relative to the masseteric fossa behind it. These features suggest that the principal axis of the temporalis fibres was nearly vertical with respect to the occlusal plane, and situated more anteriorly than is typical of extant prosimians. Similar features are seen among rodents, and are pronounced in a larger and later plesiadapoid from Europe, Plesiadapis tricuspidens1. The origin of the superficial masseter is marked by a crest on the ventral surface of the orbital margin, above the buccal edge of the second upper molar. This origin is farther forward than in most extant prosimians, and implies a more horizontal orientation for this muscle, as in lorisids.

The medial and lateral pterygoid laminae diverge widely, enclosing a large pterygoid fossa. If the origin of the medial pterygoid was restricted to this fossa, as it is in some extant members of the Insectivora, it was probably relatively larger than in extant prosimians of comparable size. If this muscle also had a superficial head arising from the medial orbital wall, as in Galago, Tarsius, Tupaia and Felis, it must have been exceptionally large. Palaechthon's well-developed anterior temporalis, enlarged medial pterygoid and horizontally oriented superficial masseter may be in part related to the use of the anterior lower incisors in protrusive prying, shovelling or other ingestive movements.

The orbital margins are deformed but largely preserved. The supraorbital shelf is well developed, and a short superior postorbital process is present. The shape of the superior orbital margin indicates that a complete postorbital bar was probably absent. The dihedral angle between orbital and midsagittal planes (measured from a sculpted reconstruction) was about 35°, and the line of intersection of these two planes must have been approximately parallel to the skull roof. In these respects, *Palaechthon* resembles terrestrial sciurids<sup>4,5</sup>. Visual-field overlap could not have been extensive.

The orbital diameter of *Palaechthon* was approximately 7 mm. This is smaller than would be expected for extant prosimians, tree shrews, elephant shrews, sciurids, dermopterans or arboreal didelphids of comparable body size. Nocturnal terrestrial foragers like *Echinosorex* and *Monodelphis* resemble *Palaechthon* in relative orbital diameter.

The interorbital breadth of *Palaechthon* is unusually great. In extant mammals, three principal factors influence this dimension. First, in animals with relatively gracile zygomata, orbital convergence necessitates reduction of interorbital breadth<sup>6</sup>. Second, interorbital breadth may be increased for the transmission of exceptional compressive stresses generated in mastication or incisal biting, as in *Daubentonia*, *Dactylopsila*<sup>7</sup>,

Alouatta<sup>8</sup> and colobines. Third, interorbital breadth may increase in conjunction with an enlargement of the olfactory fossa, as in Nasua. The last two of these factors probably operated in Palaechthon; the preserved parts of the skull demonstrate the resulting lateral position of the orbits (accentuated by the supraorbital shelf) and the large olfactory fossa.

Compared with extant prosimians and tupaine tree shrews, *Palaechthon* has a large infraorbital foramen, implying that the innervation and blood supply of the rhinarium and vibrissal roots were correspondingly well developed. The relative size of this foramen resembles that of living hedgehogs and carnivores.

In summary, the known cranial and dental remains of *P. nacimienti* imply that it relied more on tactile and olfactory information than on vision in its foraging activities. The well-developed anterior temporalis suggests that powerful occlusal forces could be exerted in mastication. The molar morphology indicates a predominantly insectivorous diet. An adaptive mode involving substantial amounts of nocturnal foraging on the forest floor is consonant with the observed morphology. Squirrel-like arboreal habits involving diurnal foraging for plant foods, or visually-directed predatory habits like those of many small marsupials or extant insectivorous prosimians, seem less likely.

We thank Dr L. Martin for the loan of specimens under his care at the University of Kansas, and Kaye Brown and Dr W. L. Hylander for comments on the manuscript.

## ADP binding to relaxed scallop myofibrils

CALCIUM regulates muscle contraction in all species which have been studied. Muscle relaxes in the absence of calcium and contracts when it is present in micromolar concentrations<sup>1-3</sup>. Contraction is caused by the interaction of myosin with ATP and with the actin of the thin filament, and the effect of calcium is to modulate this interaction<sup>1-8</sup>. Although these features apply to all muscles, the location of the calcium binding and thus the mechanism of its action differs in different phyla; regulation may be associated with the myosin, or the thin filaments or both<sup>2,3,7</sup>.

The mechanism of the myosin ATPase in vertebrate muscle, in which regulation is thin filament-linked, has been widely studied. Myosin rapidly binds and hydrolyses ATP to form a myosin·ADP·P<sub>1</sub> intermediate<sup>9,10</sup>. The breakdown of this complex is the rate limiting step of hydrolysis

and actin accelerates this rate<sup>11</sup>. Therefore, in relaxed vertebrate muscle where the actin-myosin-ADP-P<sub>1</sub> interaction is blocked by the troponin-tropomyosin of the thin filaments, ADP and P<sub>1</sub> are found bound to myosin in the steady state<sup>12</sup>.

In molluscs, on the other hand, calcium regulation is myosin-linked and it is not known whether, in the absence of calcium, the hydrolysis of ATP, itself, is blocked and myosin ADP P<sub>i</sub> is not formed, or whether myosin ADP P<sub>i</sub> is formed but its association with the thin filaments is blocked. In this study we show that in molluscs, as in vertebrates, ADP is bound to myosin in relaxing conditions.

Myofibrils were prepared from both fresh and glycerinated Aequipecten irradians striated adductor muscles. Muscles were glycerinated according to Kendrick-Jones et al.7 in a solution consisting of 50 mM NaCl, 1 mM MgCl<sub>2</sub>, 5 mM phosphate buffer (pH 7.0), 0.1 mM sodium azide and 50% glycerol, and stored at  $-20^{\circ}$  C for one month. To prepare myofibrils, muscles were homogenised in a Sorvall Omni mixer in 5 mM piperazine-N, N'-bis-2-ethanesulphonic acid (PIPES), pH 7.1, 5 mM ethyleneglycol-bis (β-aminoethyl ether)-N,N'-tetraacetic acid (EGTA), pH 7.0, 50 mM KCl and 5 mM MgCl<sub>2</sub>, and sedimented at 12,000g for 10 min. The pellet was rehomogenised in the same solution and resedimented at 500g for 10 min twice. A homogenous suspension of myofibrils, containing 15-20 mg protein ml-1, was embedded in a 1% agarose gel as previously described<sup>12,13</sup>. Blocks of the gel (100 to 200 nl) were cut out and incubated at 2° C in relaxing solution containing 14C-ATP at 200 mCi mmol<sup>-1</sup>; <sup>14</sup>C-mannitol was used as a volume

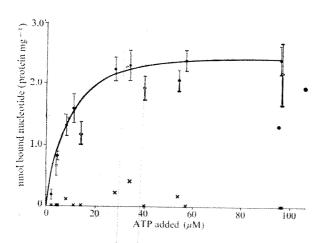

Fig. 1 Nucleotides bound by scallop striated muscle in relaxing conditions in the presence of different concentrations of MgATP. Conditions: 5 mM PIPES buffer; 5 mM EGTA; 5 mM MgCl<sub>2</sub>; 50 mM KCl; 4 mM creatine phosphate; phosphocreatine kinase (5 mg ml<sup>-1</sup>). 1 mM sodium azide 0-100 μM <sup>14</sup>C-ATP, <sup>14</sup>C-mannitol, pH 7.1, i=0.095, 2° C. ADP bound to glycerinated, ♠, and fresh, ○, myofibrils; ×, corresponding ATP binding; vertical bars, ± 5% fiducial limits of eight assays.

marker and an ATP regenerating system was included in the medium (Fig. 1). After 3 min, the gel blocks were transferred to trichloroacetic acid and the bound nucleotide content was determined. The details of this procedure have been described in a previous paper  $^{12,13}$ . The myofibrillar ATPase (that is, Mg-ATPase) was measured in a pH stat as previously described at  $2^{\circ}$  C and  $25^{\circ}$  C.

In relaxing conditions (ATP, no calcium) where the Mg-ATPase was at least 97% inhibited, myofibrils from glycerinated scallop striated muscle bound a large quantity of ADP and only minimal amounts of ATP and AMP (Fig. 1). Assuming a simple binding, a nonlinear regression analysis

of the data<sup>14</sup> showed a maximum ADP binding of 2.69±0.15 nmol per mg protein, and the dissociation constant was 9 mM±2 s.e. The amount of ADP bound was almost identical to the estimated quantity of myosin sites in the muscle (2.75 nmol mg<sup>-1</sup> based on a 62% myosin content<sup>8</sup> and a weight of 225,000 daltons per active site<sup>13,18</sup>). Myofibrils from fresh muscle were about 90% calcium sensitive, bound slightly less ADP (2.45±0.15 nmol mg<sup>-1</sup>) and had a slightly higher dissociation constant (12±3 mM). The smooth ('catch') muscle of Aequipecten, which has a smaller myosin content than the striated muscle, also bound only ADP in relaxing conditions, with a maximum binding of 0.75 nmol per mg protein.

These results show that the steady-state intermediate of relaxed myosin ATPase of scallop muscle is M-ADP (presumably the P<sub>1</sub> moiety of ATP is also bound in this complex<sup>9,10,12</sup>); thus, the decomposition of this complex is rate limiting. It follows that calcium activation cannot act at the hydrolytic step: M·ATP=M·ADP·P, as this reaction is not rate limiting, but must affect the subsequent reaction of M·ADP·P<sub>1</sub> with actin. It was previously shown that scallop myosin has a reduced apparent affinity for actin in relaxing conditions; in this paper the cause of this has been explained. From the results of nucleotide binding experiments on vertebrate, insect, and molluscan muscle, it seems likely that calcium regulates the actomyosin ATPase cycle at the same step in each, even though the control site may be located on myosin as in scallop7, on the thin filaments as in vertebrates1.2,23,12, or on both the myosin and the thin filaments as in insects, such as Lethocerus3,12,17

## In vitro activity of cells from genetically lethal embryos of Drosophila

MUTATIONS that affect particular embryological events can help to elucidate the developmental interactions and cellular and biochemical mechanisms. In *Drosophila* much of the work<sup>1,2</sup> in developmental genetics has been done on strains that carry chromosomal aberrations, particularly deficiencies; or on strains that segregate aneuploid progeny, such as X-linked stocks.

Deep orange (dor) is an X-linked (1-0.3) recessive mutant
• of D. melanogaster<sup>3</sup>. In addition to an alteration in pteridine
pigments of the eye<sup>4</sup>, dor causes a peculiar type of sterility<sup>3-6</sup>.
When dor females are mated to dor males, all offspring die
during the course of embryonic development. When heterozygous females are mated to dor males, however, all of the
expected progeny types survive and develop normally. This
indicates that the viability of dor embryos depends on the
maternal as well as the zygote genotype.

Thus dor embryos survive only if an essential developmental component is provided by the egg cytoplasm produced by heterozygous mothers. This repair of dor egg defect by the essential component has been recently confirmed by an injection experiment in which cytoplasm from unfertilised normal eggs was injected into dor embryos at the syncytial preblastoderm stage of development? The present experiment reveals that some types of cells from dor embryos proliferate actively and manifest their function for prolonged periods when they are cultured in a chemically defined medium with some macromolecular supplementations, especially when the wild-type egg extract was added to culture medium.

The dor strain used was a balanced stock carrying C1B X chromosome. Eggs collected from matings of dor/dor females and dor/Y males were dechorionated by a 6-min treatment with 3% sodium hypochloride. The eggs were then rinsed with distilled water and transferred to physiological salt solution, in which they were allowed to develop at 25° C. The developmental stages of dechorionated eggs were readily determined through the transparent vitelline membrane under a binocular microscope. Among 463 eggs obtained from the above matings, 19 (4.1%) died before gastrulation, 179 (38.7%) died by abnormal gastrulation, 204 (44.0%) died after the stage of sac-like midgut, 61 (13.2%) died after muscular movement and none hatched.

Dor embryos which developed beyond gastrulation were sterilised in 70% ethyl alcohol for 10 min, rinsed three times with sterile salt solution, and used for in vitro cultivation. The procedure for cultivation of Drosophila embryonic cells has been previously described. Embryos were torn into small fragments with a pair of fine needles and cultured in T-5 flasks in medium K-17 (ref. 9) supplemented with 0.1 mg ml<sup>-1</sup> fetuin and 15% foetal bovine serum.

After several hours of cultivation, spindle-shaped muscle cells came out from the cut ends of tissue fragments (Fig. 1a).

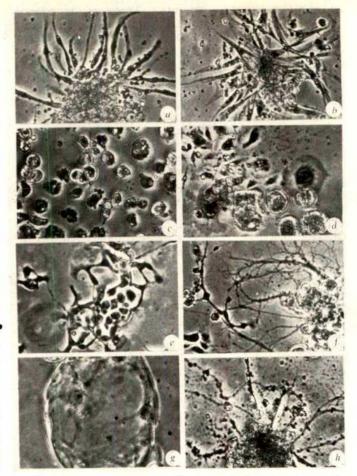

Fig. 1 Various types of cells from dor lethal embryos of Drosophila melanogaster (×450). a, Muscle cells after 4-d cultivation; b, muscle cells pulsating synchronously after 34-d cultivation; c, epithelial cells with many cytoplasmic granules after 3-d cultivation; d, epithelial cells showing chitinous pigmentation after 7-d cultivation; e, fibroblastic cells after 3-d cultivation; f, nerve cells with network of nerve fibres after 8-d cultivation; g, a cellular sphere after 10-d cultivation with wild-type egg extract; h, nerve fibres with deposits of small droplets on them after 10-d cultivation with wild-type egg extract.

They were 50–100 µm in length and had an ovoid nucleus. They gradually increased in number around the original tissue fragments. The formation of syncytial complexes, which has been observed in cultures of wild-type embryonic cells, was not found in cultures of dor embryonic cells. Some of these muscle cells pulsated at a particular interval for each cell. When they were in contact with each other, they pulsated synchronously. This pulsation continued for more than 5 weeks under culture conditions employed (Fig. 1b).

Flat polygonal epithelial cells were also found at the initial

<sup>\*</sup> Oregon-R egg extract.

stage of cultivation. They grew slowly and increased gradually in size with many cytoplasmic granules (Fig. 1c). It seemed that their maturation proceeded. After cultivation for 7 d a chitinous pigmentation (coloured brown) was observed in the cytoplasm of some cells (Fig. 1d).

Fibroblastic cells which were most motile appeared after 3-d cultivation (Fig. 1e). They migrated rapidly by extension and contraction of their cytoplasmic processes. In cultures of wild-type embryonic cells it has been found that fibroblastic cells formed baloon-like cellular spheres8. In the present cultures of dor embryonic cells, however, no such cellular spheres were observed.

Some nerve fibres extended from nerve cells. They increased in length and formed many branches. After cultivation for 8 d nerve fibres made contact with each other and formed a nerve network (Fig. 1f). In further cultivation, however, the deposition of small droplets, which has been found in cultures of wild-type embryonic cells and seems to be some secretion from the nerve fibres, were not observed in cultures of dor embryonic cells.

In cultures of wild-type embryonic cells, some groups of extremely small cells which were epithelial in morphology, about 3 µm in diameter and seemed to be imaginal disk cells has been observed. In the cultures of dor embryonic cells, no such small cells were detected in identical culture conditions.

The characterisation and phenotypic expression of cell types appearing in cultures of dor embryonic cells are summarised in Table 1. In this table, the findings in cultures of wild-type embryonic cells are also listed for comparison. This indicates that mesodermal cells such as muscle cells and fibroblastic cells from dor embryos were maintained in a functionally active state for a relatively extended period over the prospective lethal phase of the dor embryos, although some defects in properties such as syncytium formation of muscle cells were found. On the other hand, ectodermal cells such as epithelial cells, small cells, and nerve cells grew scarcely and manifested only a part of their respective behaviour and functions in the in vitro conditions employed.

Unfertilised eggs collected from the wild-type strain, Oregon-R, were homogenised in culture medium and centrifuged at 2,000 r.p.m. for 15 min. When dor embryonic cells were cultured in medium containing the wild-type egg extract (100 eggs ml-1) obtained by this method, defects in behaviour and functions of ectodermal cells were found to be almost repaired (Table 1); syncytium formation of muscle cells, formation of cellular spheres (Fig. 1g), and droplet formation on nerve fibres (Fig. 1h). Even in cultures with the wild-type egg extract, the growth and formation of regular arrangement of small cells were still not observed.

Since the dor mutant is known to be abnormal in pteridine metabolism, some pteridines may have an effect on the normal growth and differentiation of dor embryonic cells. The procedure for in vitro cultivation of dor embryonic cells seems to offer an experimental approach to analysing the effective substances which are produced by the normal allele of dor gene and may be necessary for normal development.

I thank Miss M. Maeda for her assistance in the experimental work. The dor strain used was provided by Dr A. Garen, Yale University.

## Is calcium ionophore a universal activator for unfertilised eggs?

We have previously exposed sea urchin eggs to micromolar amounts of the divalent transporting ionophore A23187, and observed every parameter of normal fertilisation. The cortical reaction with elevation of the fertilisation membrane, the plasma membrane conductance changes, the respiratory burst, and increases in protein and DNA synthesis were all initiated in the usual fashion. These activations of Lytechinus pictus and Strongylocentrotus purpuratus eggs were independent of the ionic composition of the external solutions<sup>1</sup>. A23187 seemed to act by releasing intracellular Ca2+, for eggs preloaded with 45Ca showed a twentyfold increase in 45Ca-efflux when activated by ionophore or fertilisation<sup>1</sup>. Measurements of free and bound calcium and magnesium in homogenates of unfertilised eggs showed that most of the Mg2+ was already available in soluble form, whereas the Ca2+ was sequestered but available for release<sup>1</sup>. After we found that 50 µM A23187 could activate eggs of the mollusc Acmaea insessa and the protochordate Ciona intestinalis to undergo several abnormal cleavages, we wondered whether ionophore activation might be a general phenomenon. To our knowledge artificial parthenogenesis has not been obtained with Acmaea and Ciona eggs by other methods. We have now found that calcium ionophore activation is common to several species widely separated phylogenetically.

We used three species whose egg activation has been well described in the literature; the bat-star, Patiria miniata (Asteroidea), the toad, Xenopus laevis (Anura), and the hamster, Mesocricetus auratus (Mammalia). A 5 mM stock solution of A23187 (obtained from R. L. Hamill, Eli Lilly Co., Indianapolis) was prepared in dimethylsulphoxide (DMSO) and stored in the dark. Appropriate controls were run with DMSO and indicated no effect. When the stock ionophore solution was diluted for use with occutes, the solutions were stirred continuously to ensure good mixing. since the ionophore is very insoluble in water and there is some precipitation. Final concentrations given here are therefore maximum estimates.

Isolated ovaries of P. miniata were teased to free the operates. which were stored as premeiotic cells in filtered seawater at 16° C. When oocytes were first incubated in the hormone 1-methyladenine (1-MA)  $1\times10^{-5}M$  for 30 min to induce maturation<sup>2-4</sup>, exposure to ionophore (5-25 μM) initiated a cortical reaction indistinguishable from that initiated by sperm.

Meiosis continued in these activated eggs and two polar bodies were produced as in eggs treated with 1-MA only. Usually, the activated eggs did not divide. After 20 h more than 90% were still one cell. One two-cell and one 12-16-cell stages were seen.

Ionophore activation did not depend on exogenous calcium. Eggs pretreated with 1-MA could be activated by 5-25 µM ionophore in Ca2+-free seawater (Na+ substituted for Ca2+ plus 2 mM ethylene glycol bis(β-aminoethyl ether)N,N,N'N'tetraacetic acid (EGTA)).

X. laevis females were treated as described by Wolf and Hedrick<sup>5</sup>, to obtain eggs, which were expressed into De Boer's solution (0.11 M NaCl, 0.0013 M KCl, 0.00440 M CaCl<sub>2</sub> plus solid NaHCO<sub>3</sub> to pH 7.2) and 5-10 oocytes per ml were placed into small syracuse dishes. Criteria of activation

<sup>\*</sup>Percentage observed with both cortical reaction and pigment migration.

were first, elevation of a fertilisation membrane and, second, contraction or capping of pigment from vegetal to animal hemisphere.

As Table 1 shows, 5-10 µM A23187 elicited both cortical reactions and pigment migration within 2-3 min: both changes were complete by 5-13 min. These times are similar to those observed after normal fertilisation. The same activations were observed in Ca<sup>2+</sup>-free De Boer's medium supplemented with 2 mM ethylene-diaminetetraacetic acid (EDTA).

Mature unfertilised eggs of *M. auratus* were obtained from oviducts of unbred females 15-17 h after injection of human chorionic gonadotrophin<sup>6</sup>. The eggs were freed from surrounding cumulus cells by treatment for 15 min (25° C) with 0.1% bovine testicular hyaluronidase (300 USP U ml<sup>-1</sup>; Nutritional Biochemicals) in Biggers, Whitten and Whittingham (BWW) medium and rinsed thoroughly with Ca<sup>2+</sup>-Mg<sup>2+</sup>-free BWW. (The medium was modified by replacing albumin with 0.2% polyvinylpyrrolidone. *pH* was adjusted to 7.3 by addition of a small amount of N/5 HCl.)

The eggs were placed in 0.2 ml of either normal or Ca<sup>2+</sup>-Mg<sup>2+</sup>-free BWW (pH 7.3) containing freshly diluted 3–20 μM A23187 and incubated under mineral oil (Squibb) in a watchglass in an air atmosphere at 37°-38° C. At various times the eggs were examined with a phase contrast microscope to determine the condition of cortical granules and female pronucleus.

Continuous exposure to high concentrations (10-20 µM) of A23187 was deterimental to the eggs, resulting in disintegration of the cytoplasm. Exposure to a lower concentration (3 µM), activated the eggs, the extent of activation being greater in Ca2+-Mg2+-free media (Table 2a) than in the complete medium (Table 2b). The rate of cortical granule breakdown and pronuclear development in Ca2+-Mg2+-free media was comparable with the rate in sperm-activated eggs8. The extent of cortical granule breakdown, however, was usually less in A23187-activated eggs than in those activated by sperm. Qualitative estimates showed 80-90% breakdown of granules in eggs activated in Ca<sup>2+</sup>-Mg<sup>2+</sup>-free media and a less complete breakdown in eggs activated in the complete medium. Activation of nuclear events were also slower in the complete medium. These differences may have resulted from decreased solubility of the ionophore in the presence of divalent cations.

Brief exposure to A23187 induced activation of the eggs. For example, when the eggs were exposed to  $3-10~\mu M$  A23187 in Ca<sup>2+</sup>-Mg<sup>2+</sup>-free BWW for 2 min then washed and left in Ca<sup>2+</sup>-Mg<sup>2+</sup>-free BWW, they all showed breakdown of the cortical granules within 30 min and well developed female pronuclei were formed in 2 h.

The activation by A23187 induced a zona reaction identical to that resulting from normal fertilisation. This is a change in the zona pellucida surrounding the egg, which prevents sperm penetration<sup>9, 10</sup>. Unfertilised cumulus-free eggs were rinsed with Ca2+-Mg2+-free BWW washed and left in Ca2+- $Mg^{2+}$ -free BWW, incubated for 2 min in 3-10  $\mu M$  A23187 in  $Ca^{2+}$ -Mg<sup>2+</sup>-free BWW for 30 min at  $37^{\circ}$ -38° C. The eggs were then transferred to a medium containing capacitated hamster sperm. The spermatozoa were incubated in a mixture of heat-inactivated rabbit serum and Tyrode solution (1:1) for 3-4 h to induce capacitation and the acrosome reaction before mixing with the eggs. The eggs were incubated with capacitated sperm at 37°-38° C for 2 h. No spermatozoa penetrated the zonae pellucidae of these eggs (45 eggs tested). Control eggs (38 tested) treated in the same way except for exposure to A23187 were all penetrated by spermatozoa.

Calcium has long been implicated to some extent in the activation of marine eggs. The usual procedure to induce some degree of parthenogenetic development was to substitute high concentrations of calcium for sodium in artificial seawaters<sup>11, 12</sup>. Also consistent with a Ca<sup>2+</sup> involvement was the observation that an increase in free cytosol calcium occurs in eggs which have just been fertilised<sup>13, 14</sup>. Previous results with the sea urchin indicate that activation can result from the release of intracellular stores of calcium induced by a calcium ionophore<sup>1</sup>. The Ca<sup>2+</sup>-ionophore can also activate a wide

variety of species of eggs as reported here; and these activations of marine, amphibian and mammalian oocytes are also independent of external calcium. We now propose that release of intracellular ionic calcium may be the universal factor promoting activation of egg metabolism at fertilisation.

## Concanavalin A-induced agglutination of Acanthamoeba

VIRULENT strains of Acanthamoeba produce cytopathic effects in mammalian tissue cultures<sup>1-3</sup>, and cause acute meningoencephalitis in laboratory animals after intranasal inoculation. In humans, Acanthamoeba seem to produce cerebral lesions in defence-weakened individuals<sup>4-7</sup>. We have begun studies of the cell surface of Acanthamoeba since virulent strains must make direct contact with a host cell before initiation of degenerative changes in mammalian tissue cultures2,3. The sensitivity of avirulent and virulent strains to concanavalin A (con A)-induced agglutination was investigated first as there was no evidence that carbohydrate-containing components were exposed at the cell surface of Acanthamoeba. Our results indicate that both avirulent and virulent Acanthamoeba were sensitive to con A-induced agglutination. In contrast to the results of studies of avirulent and virulent Entamoeba histolytica<sup>8</sup>, however, the avirulent strain was more sensitive to con A.

The avirulent Neff strain of A. castellanii and a virulent A-3 strain of A. culbertsoni<sup>10</sup> were cultured under constant axenic, suspension growth conditions as described previously11. The strains were removed from exponential cultures of approximately the same age, concentrated by centrifugation and washed three times with calciummagnesium-free-phosphate-buffered saline (CMF-PBS). Cells  $(5 \times 10^{5} \text{ ml}^{-1})$  were placed in Microtest tissue plates (Falcon) and, unless otherwise indicated, treated with the specified concentration of con A (crystallised three times; Miles-Yeda) with constant agitation at 22° C for 5 min. Agglutination was scored immediately on a scale of 0 to 4+ under an inverting microscope. Studies with ferritin-labelled con A (prepared as before12) were performed either at 4° C or 22° C, using solutions pre-equilibrated before addition of the cells. After incubation for 30 min, cells were maintained at 4° C or 22° C during three washes with CMF-PBS and preparation for electron microscopy.

Table 1 shows that under identical conditions, the avirulent strain of Acanthamoeba consistantly exhibited twice the sensitivity to con A-induced agglutination than that shown by the virulent strain. Simultaneous addition of 3.5 mM α-methyl-D-mannopyranoside abolished the agglutination of both strains. Nonspecific sugars such as lactose affected agglutination only at significantly higher concentrations (Table 1).

We further investigated whether agglutination could be affected by various treatments. Agglutination of both strains, tested at different concentrations of con A (avirulent: 0.5, 5 or 25 μg ml<sup>-1</sup>; virulent: 5, 25, or 50 μg ml<sup>-1</sup>), was unaffected after pretreatment for 15 min at 31° C with trypsin or pronase (0.0001 to 0.01 mg ml-1), neuraminidase (Vibrio cholera; 15 U ml-1; General Biochemicals) or ethylenediaminotetraacetic acid (0.1-1.0 mM). On the other hand, both strains pretreated for 15 min at 31° C with. sodium cyanide (16 mM), sodium arsinite (5 mM) or glutaraldehyde (0.25%) showed no agglutination after exposure to the above concentrations of con A. These results suggested that con A-mediated agglutination of Acanthamoeba might depend on free mobility of receptor sites in the membrane and also require ATP. Glutaraldehyde inhibition of con A-induced agglutination of transformed 3T3 fibroblasts has been explained similarly 13,14; however, ATP apparently is not necessary for con A-induced agglutination of these cells14.

As Fig. 1 shows, agglutination of both strains also was inhibited significantly at temperatures of 15° C or less. The temperature sensitivity further appeared to depend on the con A concentrations, and cells treated with con A at 5° C agglutinated rapidly when the temperature was raised to 22° C. Although inhibition of Acanthamoeba agglutination at low temperatures might be due to an alteration in the fluidity of the membrane14, we cannot yet exclude the possibility that the inhibition is due to some other cellular alteration, for example, inhibition of an essential enzyme(s). Since con A has been shown to bind at low tempera-

tures14,15, Acanthamoeba was treated with ferritin-labelled con A at 4° C or 22° C in an attempt to explain the greater agglutination of avirulent compared with virulent cells. In accordance with explanations for the similar sensitivity of transformed or trypsin-treated 3T3 fibroblasts compared with the normal fibroblast, the difference might be due to the amount of con A bound14,16, topographical distribution of the receptor sites17, and/or mobility of the receptor sites in the lateral plane of the membrane 13,14

Figure 2 shows high magnification micrographs of the cell surfaces of avirulent and virulent Acanthamoeba after exposure to ferritin conjugate at 4° C. The conjugate was

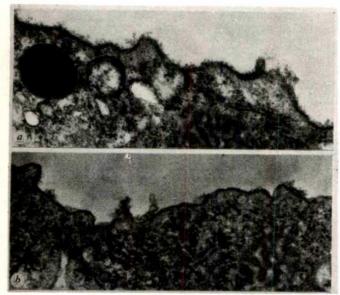

Fig. 2 Electron micrographs of thin sections of avirulent (a) or virulent (b) Acanthamoeba exposed to ferritin-labelled con A (80  $\mu$ g ml<sup>-1</sup>) at 4° C. Cells were placed at 5 × 10<sup>3</sup> cells ml<sup>-1</sup> in pre-equilibrated solutions of ferritin conjugate and incubated for 30 min. After several washes in CMF-PBS, cells were fixed with glutaraldehyde and osmium tetroxide, embedded in Araldite, and the sections stained with uranyl acetate and lead citrate  $(a, \times 36,480; b, \times 43,920)$ .

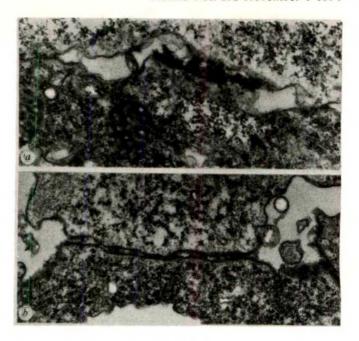

Fig. 3 Electron micrographs of thin sections of avirulent (a) or virulent (b) Acanthamoeba exposed to ferritin-labelled con A (40  $\mu$ g ml<sup>-1</sup>) at 22° C. After incubation in the conjugate for 30 min, samples of cells were processed as described in Fig. 2. The micrograph shown in (b) was typical of the contact regions of both agglutinated virulent and avirulent amoebae. The micrograph in (a) illustrates the electron-dense, amorphous material with associated ferritinlabelled con A which was found occasionally in contact regions of agglutinated avirulent amoebae (a, ×29,280;  $b, \times 19,200$ ).

distributed randomly with only an occasional cluster of the ferritin label at the surface of the avirulent amoebae (Fig. 2a). In contrast, the surface of the virulent cells appeared almost devoid of associated ferritin-labelled con A. High magnification revealed, however, that the conjugate was localised in discrete clusters on the virulent amoebae surface (Fig. 2b). In both avirulent and virulent cells, little or no label was found within the cytoplasm but, when present, it was enclosed in small membrane-bound vacuoles (Fig. 2a). Sections of control preparations, in which cells were exposed only to ferritin, showed no nonspecific binding of ferritin molecules.

Figure 3 shows electron micrographs of avirulent and virulent Acanthamoeba exposed to the ferritin-labelled con A at 22° C and illustrates regions of contact between agglutinated cells in the samples. High concentrations of the conjugate were observed routinely on membrane areas immediately adjacent to and at contact points of both agglutinated avirulent and virulent amoebae. Areas more distal to the contact regions were relatively free of conjugate. Figure 3b, although showing agglutinated virulent amoebae, is typical of the appearance of most contact regions between avirulent cells. Additionally, however, contact regions of avirulent amoebae occasionally contained large amounts of electron dense, amorphous material with associated ferritinlabelled con A (Fig. 3a). Although not illustrated, the ferritin conjugate was clustered on the surfaces of nonagglutinated, single cells in samples of both avirulent and virulent cells treated with the conjugate at 22° C.

In view of the uniform distribution of ferritin conjugate at the surface of avirulent amoebae exposed at 4° C, the greater agglutination of this strain cannot be attributed to the presence of pre-clustered con A receptor sites, which may account for the greater sensitivity of the transformed 3T3 fibroblast to con A17. Instead, the greater sensitivity of the avirulent strain probably results because more con A receptor sites (mannose-like residues) are exposed at the surface than on the virulent strain. A greater mobility of the con A receptor sites in the membrane of the avirulent strain may contribute partially to the greater agglutination; however, since the virulent strain appeared capable of clustering con A receptor sites, as evidenced by the large aggregates associated with contact points between agglutinated cells in samples exposed to ferritin conjugate at 22° C, the difference in the membrane fluidity of the strains may be minimal.

## Dissociation of increased hexose transport from initiation of fibroblast proliferation

ALTERATIONS in the permeability of the surface membrane might play a key role in the control of DNA synthesis and cell division<sup>1-3</sup>. Evidence that changes in hexose transport might participate in growth control comes from reports that uptake of certain hexoses (1) increases after transformation by tumour viruses4-6, and correlates with the expression of the transformed phenotype<sup>7</sup>; (2) decreases when untransformed fibroblasts reach a density-inhibited monolayer<sup>5,8</sup>, and (3) rapidly increases after initiating cell division with serum or other agents<sup>8,9</sup>. We now report, however, that increased hexose transport and initiation of proliferation can be uncoupled in density-inhibited 3T3 mouse fibroblasts. Levels of cortisol which initiate DNA synthesis and division of these cells18,111 actually decrease hexose transport. In addition, some serum components increase hexose transport without initiating proliferation.

Mycoplasma-free 3T3 Swiss mouse fibroblasts (clone 42) were grown as previously described12. Medium components were purchased from Gibco. Density-inhibited cultures were prepared by plating 30 or 50 mm Nunc plastic tissue culture dishes with  $1.7 \times 10^4$  cells cm<sup>-2</sup> in 2 ml (for 30

Table 1 Stimulation of DNA synthesis and cell division by cortisol and serum

Cells were grown to confluency and cortisol or fresh serum was added to cultures. DNA synthesis and cell number were determined at 24 and 72 h respectively after these additions as previously described 10.

mm dishes) or 4.5 ml (for 50 mm dishes) of culture medium containing 10% calf serum. The cells grew to a final saturation density of  $3.5 \times 10^4$  to  $4.2 \times 10^4$  cells cm<sup>-2</sup> over 3 d. Hexose uptake was measured using the nonmetabolisable hexose analogues 3-O-methyl-p-glucose and 2-deoxy-D-glucose. Both of these sugars are transported into cells by facilitated diffusion. Kinetic studies have indicated that they are transported by the same system that transports glucose.

To determine the extent of correlation of initiation of proliferation and increased hexose transport, we added fresh serum (5.0%) or the glucocorticoid steroid hormone, cortisol (3.0×10<sup>-6</sup> M) and measured DNA synthesis, cell number and uptake of hexose analogues. These additions caused similar increases in the rate of DNA synthesis at 24 h and cell number at 72 h (Table 1), indicating that under these conditions measuring DNA synthesis was an \* accurate measure of proliferation. As Fig. 1 shows, however, initiation of DNA synthesis in density-inhibited 3T3

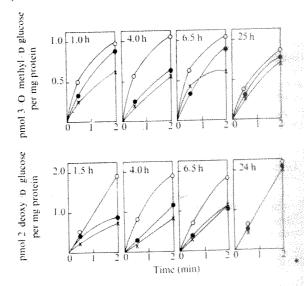

Fig. 1 Time course of 3-O-methyl-p-glucose and 2-deoxy-pglucose uptake by control density-inhibited 3T3 cultures (a) and parallel cultures treated with 5% serum (), or 3 µM  $cortisol(\times)$ . Times in hours refer to times after serum or cortisol treatment. Hexose uptake was measured by removing the growth medium, rinsing the cells once with PBS at 37° C and adding <sup>3</sup>H-3-O-methyl-D-glucose (2 µCi; 3.7 Ci mmol<sup>-1</sup>) or <sup>3</sup>H-2-deoxy-D-glucose (2 µCi; 7.2 Ci mmol<sup>-1</sup>) in 2.0 ml PBS. Cultures were incubated at 37° C for the times indicated on the abcissa. They were then immediately rinsed four times with PBS at 4° C. Less than 5% of the intracellular radioactivity was removed by this rinsing procedure. Further rinsing did not remove significant amounts of radioactivity from the cells. Acid-soluble radioactivity was extracted from the cells for one hour with 10% trichloroacetic acid (TCA) at 4° C, and measured in a liquid scintillation counter. Uptake measurements were corrected for radioactivity nonspecifically associated with the cells which was consistently less than 10% of the uptake value. Nonspecific association was determined by adding labelled hexose in PBS to cells at 4° C. This was immediately aspirated, and cultures were processed as described above for uptake measurements.

Table 2 Relative stimulation of DNA synthesis and hexose uptake by different lots of commercial serum

			wommin	ciai sciaini

After growth to confluency, 5% fresh calf serum was added to cultures. Uptake of ( $^{3}$ H) 2-deoxy-D-glucose (0.5  $\mu$ Ci ml $^{-1}$ ; 7.2 Ci mmol $^{-1}$ ) was measured during a 1-min pulse 4 h after the addition of serum as described in the legend to Fig. 1. DNA synthesis was measured at 24 h $^{10}$ . Protein was measured as previously described $^{19}$ .

fibroblasts was not always accompanied by increased hexose uptake. Addition of fresh serum to a final concentration of 5% brought about an increase in uptake of both 3-O-methyl-D-glucose and 2-deoxy-D-glucose by 1 h. The increase was maximal by 4-6 h and declined to values characteristic of density-inhibited cells by 24 h. This result confirms earlier findings. In contrast to serum, cortisol inhibits hexose uptake by certain cells 13,14. Indeed, Fig. 1 shows that  $3 \times 10^{-6}$  M cortisol, a concentration which initiated DNA synthesis and division similar to 5% serum (Table 1), actually brought about a small decrease in transport of both hexose analogues by density-inhibited 3T3 fibroblasts. Figure 2 shows that this transport decrease occurred with several cortisol concentrations which initiated DNA synthesis. Thus, an increase in hexose transport is not necessary for subsequent proliferation.

While 2-deoxy-D-glucose has been commonly used to measure glucose transport, it has the disadvantage of being phosphorylated. Thus, the intracellular radioactivity represents the sum of the phosphorylated and unphosphorylated forms of this sugar, and altered rates of transport might actually reflect altered phosphorylating activity. Since we obtained similar results with 3-O-methyl-D-glucose, which is not phosphorylated, the observed alterations appear to be a result of transport changes rather than phosphorylation.

To probe further the relationship between initiation of proliferation and increased hexose transport, we added various levels of fresh serum (0.025% to 25%) to density-inhibited 3T3 fibroblasts and measured 3-O-methyl-pglucose uptake, DNA synthesis and cell number. The dose-response curves in Fig. 3 show that fresh serum added to 0.5% caused a maximal increase in hexose transport but no• significant increase in DNA synthesis or cell number.

As Fig. 3 shows, higher concentrations of serum brought about increases in DNA synthesis and cell number which were roughly proportional to serum concentration. These higher concentrations caused no additional increase in hexose uptake. Thus, an early increase in hexose uptake is not sufficient by itself to initiate proliferation of density-inhibited 3T3 fibroblasts.

Additional experiments indicated that serum might contain multiple factors which affect growth and hexose uptake and that the relative activities of these factors might vary in different lots of serum. For example, dose-response studies, like those shown in Fig. 3, revealed for some lots of serum parallel increases in hexose uptake, DNA synthesis and cell number (data not shown). In addition, the relative stimulation of DNA synthesis and hexose uptake varied with different commercial serum lots (Table 2). In fact, the lot which produced the greatest stimulation of hexose uptake had the smallest effect on DNA synthesis. Moreover, various pure or partially purified fractions of serum had differential effects on hexose uptake and DNA synthesis (Table 3). Addition of fetuin (0.5 mg ml<sup>-1</sup>) produced a significant stimulation of hexose uptake but had no effect on DNA synthesis. As previously noted, cortisol stimulated DNA synthesis but not hexose uptake. Addition of insulin produced a graded increase in both responses (Table 3).

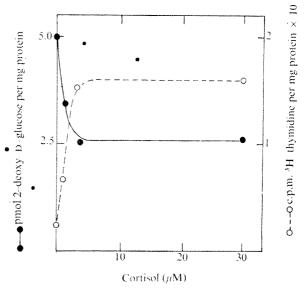

Fig. 2 Effect of cortisol concentration on hexose uptake and DNA synthesis by density-inhibited 3T3 cells. Uptake of 2-deoxy-D-glucose (●) was measured 4 h after cortisol addition as described in the legend to Fig. 1. DNA synthesis (○) was measured 24 h after cortisol addition as previously described¹¹⁰.

Table 3 Stimulation of DNA synthesis and hexose uptake by fetuin, cortisol, and insulin

	Addition	Thymidine inco	orporation	3-O-methyl-D-glucose uptake		
_		c.p.m. × 10 <sup>-4</sup> per mg protein	% control	pmol per mg protein	% control	
1	None	$1.89 \pm 0.15*$	100	$0.98 \pm 0.19$	100	
	0.5 mg ml <sup>-1</sup> fetuin	$1.96 \pm 0.15*$	103	$1.61 \pm 0.18$	166	
	10% serum	4.06±0.19*	214	$2.56 \pm 0.33$	264	
II		1.10±0.22*	100	$1.48 \pm 0.06$	100	
	3×10 <sup>-6</sup> M cortisol	$2.38 \pm 0.07$ *	216	$1.43 \pm 0.11$	97	
Ш	None 0.5 ng insulin per ml 200 ng insulin per ml	$\begin{array}{c} 0.25 \pm 0.03 \dagger \\ 0.43 \pm 0.08 \dagger \\ 0.80 \pm 0.13 \end{array}$	100 172 320	$\begin{array}{c} 1.50 \pm 0.20 \\ 1.82 \pm 0.04 \\ 2.16 \pm 0.04 \end{array}$	100 121 144	

Fetuin, cortisol or insulin were added to confluent cultures and uptake of 3-O-methyl-D-glucose (0.5 μCi ml<sup>-1</sup>; 3.7 Ci mmol<sup>-1</sup>) was measured during a 1-min pulse 4 h later as described in the legend to Fig. 1. DNA synthesis was measured as previously described<sup>10</sup>.

\* Cultures labelled for 15 min 24 h after additions.

<sup>†</sup> Cultures labelled for 6 h from 21 to 27 h after additions.

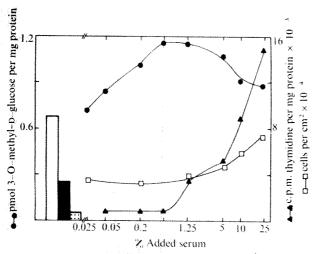

Fig. 3 Effect of concentration of added fresh serum on 3-Omethyl-D glucose uptake (●), DNA synthesis (▲) and cell number ([]). 3T3 cells were grown to confluency in medium containing 10% calf serum. Fresh serum was then added to the concentrations indicated on the abcissa. Hexose uptake was measured as described in the legend to Fig. 1 during 1 min incubation 4 h after addition of fresh serum. DNA synthesis was measured at 24 h (ref. 10) and cell number was monitored at 72 h by counting in a haemocytometer. Vertical bars show control values for density-inhibited cultures: plain bar, hexose uptake; solid bar, cell number; stippled bar, DNA synthesis.

These results demonstrate that increased hexose uptake is neither a necessary nor sufficient event for proliferation of density-inhibited 3T3 cells. •Cortisol stimulates DNA synthesis and cell division in the absence of an early increase in hexose transport, and addition of fetuin or low concentrations of serum produce increased hexose uptake without subsequent proliferation. The conclusion that increased hexose uptake and proliferation may be unlinked is consistent with the findings of Gazdar et al. that treatment of mouse sarcoma virus-transformed BALB/c 3T3 cells with dibutyryl cyclic AMP and theophylline sharply inhibited cell growth yet stimulated glucose uptake15. In addition, Rubin and Fodge have suggested that 2-deoxy-Dglucose uptake merely reflects the activity of the glycolytic pathway which is activated after stimulation proliferation16.

Early transport increases for phosphate and uridine have also been implicated in the initiation by fresh serum of proliferation of density-inhibited fibroblasts17,18. In addition, Holley has shown that 3T3 cells can be arrested in G<sub>1</sub> (or G<sub>0</sub>) by limiting phosphate in the medium, and that adding back phosphate leads to reinitiation of DNA synthesis3. De Asua et al. showed that addition of phosphate to quiescent 3T3 cells brought about a decrease in intracellular cyclic AMP levels and was required for full activation of uridine transport by serum18. They suggest that the increase in phosphate transport is a primary event in the reinitiation of growth. Cunningham and Pardee, however, showed that certain serum fractions, obtained by gel filtration on Sephadex G-200, initiated DNA synthesis in density-inhibited 3T3 fibroblasts but did not produce an increase in phosphate uptake. Moreover, fractions which increased phosphate uptake did not initiate DNA synthesis<sup>17</sup>. Thus, the early increase in phosphate transport is neither necessary nor sufficient for fibroblast proliferation brought about by fresh serum. We are probing further the possible involvement of changes in phosphate uptake in growth control processes.

We thank Mr Tom Ho for technical help. 3T3 Swiss mouse fibroblasts (clone 42) were a gift from Dr George J. Todaro. This work was supported by a grant from the National Cancer Institute. ## Dual mechanism for the action of cholesterol on membrane permeability

CHOLESTEROL, which is a widespread component of the plasma membrane, has a substantial influence on the permeability properties of lipid bilayer1-3 and cell membranes4. Although the effects of cholesterol on membrane structure are increasingly well understood<sup>5</sup> the mechanisms by which cholesterol modulates membrane permeability are obscure, mainly because it is difficult to deduce permeability properties from the knowledge of membrane structure alone.

We describe here quantitative determination of the influence of cholesterol on those variables of membrane structureelectric potential, chemical partition and rate of ionic transferwhich directly govern ionic permeability. The method useds compares the ionic conductances induced by positively charged lipophilic species to those induced by negatively charged lipophilic species. Such probing of monoolein membranes shows that although cholesterol somewhat decreases the rate of ionic transfer in these membranes, its predominant effect on ionic permeability arises by increasing the electric potential within the membrane interior, presumably by altering the strength and orientation of dipolar groups present at the membrane surface, since charged groups are absent.

The electrical conductance induced in Mueller and Rudin type7 bilayers by the lipophilic anions tetraphenylborate (TFB-) and carbonylcyanide m-chlorophenylhydrazone (CCCP-) as well as the lipophilic cations tetraphenyl phosphonium (TFP+) and 3,3'-dipropyloxadicarbocyanine iodidediO-C<sub>5</sub>-(3) (CC<sub>5</sub>+)8 was characterised as a function of the

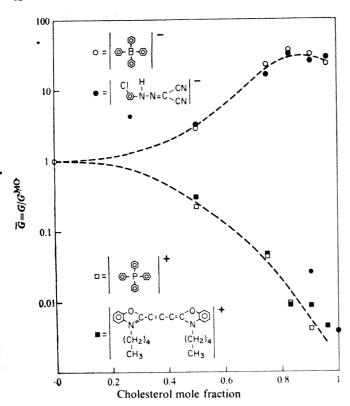

Fig. 1 Opposite effect of cholesterol on relative conductance of lipophilic cations and anions. Ordinate: relative conductance on a logarithmic scale. Abscissa: mole-fraction of cholesterol in the membrane-forming monoolein cholesterol solution. The total lipid concentration was 25 mM in decane. ○, TFB⁻; ●, CCCP⁻; □, TFP⁺; ■, CC₅⁺. For TFB⁻ equilibrium values of the relative conductance were obtained by rapid conductance measurements⁰. The supporting electrolyte was 1 M NaCl. The solutions were buffered only for CCCP, at pH 6.0 with phosphate.

cholesterol-monoolein mole-fraction in the membrane-forming lipids (25 mM in decane) using previously described techniques<sup>1</sup>. The measurements were made on membranes separating aqueous solutions of identical composition, in the limit of small applied d.c. potentials ( $\pm$  10 mV) for which conductances are voltage-independent. Membrane conductances were independent of the type (NaCl or KCl) or ionic strength ( $10^{-2}$  M to 1 M) of the supporting electrolyte, confirming the expected absence of charged polar head groups in the monoolein-cholesterol bilayers<sup>6</sup>. For each of the lipophilic ions, the relative conductance,  $\bar{G} = G/G^{MO}$ , (defined as the ratio between the conductance of a cholesterol-rich membrane, G, and that of a pure monoolein membrane,  $G^{MO}$ , formed in a solution of the same composition) was found to be independent of the pH and of the lipophilic ion concentration over a wide range.

Figure 1 plots relative conductances for CCCP<sup>-</sup>, TFB<sup>-</sup>, TFP<sup>+</sup>, and CC5+ as a function of increasing cholesterol-monoolein mole-fraction in the membrane-forming lipids. The most notable feature of Fig. 1 is the opposite effect of increasing cholesterol mole-fraction on the conductance of lipophilic anions and cations: the conductance for anions (CCCP- and TFB-) is increased about 30-fold while the conductance for cations (TFP+ and CC<sub>5</sub>+) is decreased about 100-fold. Moreover, an increase in the cholesterol mole-fraction has the same effect, within the experimental accuracy, on ions of the same charge in spite of the differences in the chemical structure and molecular shape and size of these ions (compare CCCP- with TFB- or TFP+ with CC<sub>5</sub>+). In contrast, an increase in the cholesterol mole-fraction has an opposite effect on ions with opposite charges in spite of the identical structure of these ions (compare TFB- with TFP+). Evidently it is the charge, and not the detailed chemical properties or molecular size, that determines the way in which conductance is altered by cholesterol. The lipophilic ions appear to 'sense' an increasingly positive electrostatic potential in membranes of increasing cholesterol content. Furthermore, the opposite changes seen for cations and anions in Fig. 1 imply that the membrane conductance is influenced more by this potential than by changes in membrane fluidity, which should decrease the conductance for cations and anions.

To analyse quantitatively the data of Fig. 1, consider for a lipophilic ion of valance z, the theoretical expression of the relative conductance,  $\overline{G}$ , written as a function of  $\Delta \Psi_0 = \Psi_0 - \Psi_0^{MO}$ ,  $\overline{k} = k/k^{MO}$  and  $\Delta \mu^0 = \mu^0 - \mu^{0MO}$  which respectively denote the change in the electrostatic potential  $(\Psi_0)$ , in the rate of ionic transfer (k) and in the chemical free energy of partition  $(\mu^0)$  relative to a monoolein membrane (superscript MO)<sup>6.9</sup>.

$$\overline{G} = G/G^{MO} = [\exp(-zF\Delta\psi_0/RT)][(\overline{k}\exp(\Delta\mu^0/RT)]]$$

The two factors on the right-hand side of this equation have a simple physical meaning. The first factor describes the effect of the surface potential on membrane conductance. The second factor, which is the intrinsic conductance change that would be measured if there were no surface potential change, describes the effect of diffusion and chemical partition on membrane conductance. These two factors can be evaluated separately from the relative conductance for cationic  $(\overline{G}^+)$  and anionic  $(\overline{G}^-)$  species if the second factor depends on lipid composition in the same way for cationic and anionic species.

$$\exp(F\Delta\psi_0/RT) = (\overline{G}^+/\overline{G}^-)^{-1/2}; \overline{k} \exp(\Delta\mu^0/RT) = (\overline{G}^+/\overline{G}^-)^{1/2}$$

The data of Fig. 1 show that, within experimental accuracy, a single relative conductance,  $\overline{G}^+$  and  $\overline{G}^-$  respectively, describes the effect of cholesterol on different cationic and anionic species. This, together with the fact that TFB<sup>-</sup> and TFP<sup>+</sup> have the same molecular structure, implies that the condition for separating surface potential and intrinsic conductance is satisfied for the four ions of Fig. 1.

Figure 2 plots calculated values of relative surface potential (upper part) and intrinsic conductance change (lower part) as a function of cholesterol-monoolein mole fraction. The upper part of Fig. 2 shows that in accordance with intuitive expectation the electrostatic potential increases in the membrane interior as the cholesterol-monoolein mole-fraction is increased. This surface potential increase is large; it has a maximal value of 110 mV for predominantly cholesterol bilayers compared with pure monoolein bilayers and it accounts for most of the observed permeability changes. Since the surface-potential is independent of salt concentration, and furthermore, since the lipid has no ionisable polar head groups (that is, there are only —OH

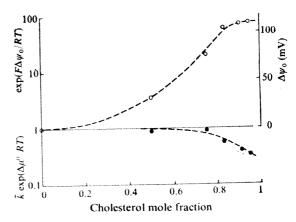

Fig. 2 Relative contributions of dipolar surface potential and intrinsic conductance changes to the effect of cholesterol on the membrane conductance induced by the lipophilic ions CCCP<sup>-</sup>, TFB<sup>-</sup>, TFP<sup>+</sup> CC<sub>5</sub><sup>+</sup> in monoolein membranes. The experimental data of Fig. 1 were analysed according to the procedure outlined in the text. Averaged values of the relative conductance for CCCP<sup>-</sup> and TFB<sup>-</sup> were used as  $\overline{G}$ <sup>-</sup>; averaged values of the relative conductance for TFP<sup>+</sup> and CC<sub>5</sub><sup>+</sup> were used as  $\overline{G}$ <sup>+</sup>.

groups, which are neutral at the pH of the experiments), the change in the surface potential must have its origin in changes in the orientation, strength and packing density of molecular dipoles at the membrane surface.

The existence of such dipolar surface-potential changes is not unreasonable10.11. Indeed, about 90 mV difference of the correct polarity is found between compensation potentials of cholesterol (near 390 mV)12 and monoolein (near 300 mV)10 monolayers spread at the air-water interface. Since a monolayer can be viewed as one half of a bilayer, the monolayer data lend independent support to the surface potentials deduced here solely on the basis of bilayer measurements, although care must be taken in making such comparisons since compensation potentials are steeply dependent on the extent to which the monolayer is compressed.

The lower part of Fig. 2 shows that cholesterol has a significant but small effect on intrinsic conductance compared with its main effect, caused by changes in surface potential (compare the left-hand scales on the upper and lower part of Fig. 2). Current-voltage measurements (that is, an exp(FV/2RT) type dependence of the current on voltage) indicate that the peak of the energy barrier13, and therefore the rate-limiting step for the permeation of CCCP-, TFB-, TFP+, and CC<sub>5</sub>+, is located in the middle of the membrane. The small effect of cholesterol on intrinsic conductance shows, therefore, that the fluidity of the middle of the membrane is not much altered by cholesterol. This supports Rothman and Engelman's conclusion that cholesterol decreases fluidity only near the membrane surface and not in the membrane interior.

It should be emphasised that the influence of cholesterol on intrinsic conductance is not always small. Preliminary experiments indicate that cholesterol decreases substantially (that is, about 100-fold) intrinsic conductance for sodium complexes of the neutral carriers, valinomycin, nonactin and triactin. Current-voltage measurements (that is, an exp(FV/2.8RT) type dependence of the current on voltage) indicate that the energy barrier is trapezoidal18 and therefore the rate-limiting step for the permeation of these complexes is located nearer to the membrane surface, where cholesterol is expected to have its maximal effect on fluidity.

Probing of cholesterol-containing monoolein bilayers reveals that cholesterol modulates membrane permeability by two distinct mechanisms: by altering (1) the electrical potential difference across the membrane-solution interface, thereby changing the partition of charged species into the membrane, and (2) the fluidity of the membrane interior, thereby changing the rate of ionic transfer and the chemical partition of the solute in the membrane. The first mechanism is expected to act in the same way on the permeability of changed species of widely different molecular structure. In contrast, the second mechanism is expected to act differently on the permeability of different ionic species depending on the structural details of the membrane and of the ion. For CCCP-, TFB-, TFP+ and CC5+ the second mechanism has only a small influence. For typical ion carriers, such as valinomycin, nonactin and triactin, its influence appears to be more prominent.

## Collagenase activity in experimental hepatic fibrosis

THE collagen fibres newly formed in experimental hepatic fibrosis and pre-cirrhosis are resorbed when the noxic stimuli have been removed1. In investigating the mechanism of genesis and resorption of collagen fibres in experimental hepatic fibrosis2,3 we have found using electron microscopy that the collagen fibres are degraded extracellularly and partly enguited by Kupffer cells and/or macrophages<sup>4,5</sup>. Within these cells digestion of collagen fibrils or degraded collagen fibrils may occur in lysosomes6.

Native collagen is resistant to all known proteolytic enzymes except collagenase, which is operative at neutral pH under physiological conditions. The first animal collagenase was isolated7.8 from the culture fluid of tadpole skin. Subsequently, collagenase was found in the culture fluid of many kinds of tissues, such as skin, postpartum rat uterus, bone, human gingiva, cornea and synovium, and in the synovial fluid from patients with rheumatoid arthritis. Collagenase has not yet been definitively observed in the liver of either animals or humans10. Here we report the presence of collagenase in rat liver and increased collagenase activity in experimental hepatic fibrosis induced by carbon tetrachloride.

Fifty female Wistar strain rats, with an average weight of 150 g, received subcutaneous injection of 0.3 ml of 50% CCI4 in olive oil per 100 g body weight, twice a week. Ten control rats were not treated. Nine to twelve rats were killed at 3, 6 and 20 weeks after the initial administration of CCl<sub>4</sub>. Diced specimens (2×2 mm) of rat liver were removed under sterile conditions and transferred immediately to 105 mm Petri dishes with sterile mammalian Tyrode's solution to which had been added 150 U penicillin ml<sup>-1</sup> and 140 µg streptomycin ml<sup>-1</sup>. They were washed repeatedly in mammalian Tyrode's solution for 24 h until they could be implanted on collagen substrate.

Salt-extracted collagen was prepared according to the method of Kang et al.11. The skin from young, growing Wistar strain rats was used as the source of collagen. The purity of saltextracted collagen was confirmed by disc electrophoresis and analysis of amino acid composition (manuscript in preparation). The assay method was similar in principle to that devised by Gross and Lapiere'. Two hundred and fifty microlitres of 0.1% collagen in cold mammalian Tyrode's medium was poured into microdishes 12 mm in diameter and 3 mm deep, and incubated at 37°C for at least 3 h. The reconstituted collagen gels were formed and were not digested by 50 µg of either trypsin, papain or pepsin (manuscript in preparation). Diced specimens of rat liver were placed on the rigid opalescent gel and incubated at 37° C for 72 h with mammalian Tyrode's solution in the outer ring (21 mm internal diameter and 5 mm deep) in a moist chamber containing 90% O<sub>2</sub> and 10% CO<sub>2</sub>. The lysis area around the explant was observed daily and the sterility of the culture was frequently confirmed.

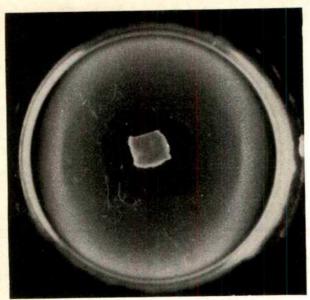

Fig. 1 Culture of rat liver treated with CCl4 for 6 weeks showing area of lysis around explant (magnification ×5.8).

In the ten non-treated rats, two livers demonstrated weak activity, five livers minimal activity and another three livers did not show appreciable lysis. Thus untreated rat livers have weak collagenolytic activity.

Microscopically the rat livers treated with CCl4 for 3 weeks showed slight to moderate periportal fibrosis. Six weeks after the initial administration of CCl4, fibrous septa were formed connecting portal tracts with the central canal containing a tributary of the hepatic vein. After 20 weeks, the rat liver showed the typical features of cirrhosis including regenerative nodules. Collagenolytic activity increased slightly in the initial stage of hepatic fibrosis and markedly in the extensive fibrosis. Figure 1 illustrates lysis of the collagen substrate surrounding an explant of rat liver treated with CCl4 administration for 6 weeks. The collagenolytic activity in the irreversible cirrhotic stage was poor compared with the activity in the rat liver treated with CCl4 for 6 weeks.

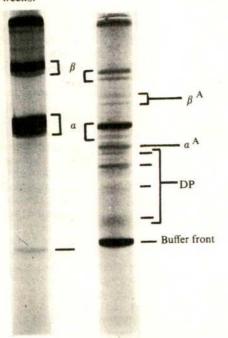

Fig. 2 Acrylamide gel electrophoresis patterns of products from incubations of collagen with rat liver treated with CCI<sub>4</sub> for 6 weeks (right) and without explant (left);  $\alpha$ , monomer;  $\beta$ , dimers;  $\alpha^{A}$ ,  $\beta^{A}$ , degradation products of  $\alpha$  and  $\beta$  respectively; DP, degradation products of lower molecular weight.

Acrylamide gel electrophoresis patterns of products from incubations of the collagen gel with rat liver treated with CCl<sub>4</sub> for 6 weeks are shown in Fig. 2. The control pattern consists of monomers (α), dimers (β) and higher molecular weight species. Incubation of collagen with the pre-cirrhotic rat liver at 35° C resulted in discrete products of α and β: α<sup>A</sup> and β<sup>A</sup> and degradative products of lower molecular weight which are similar to those seen with other animal collagenases12,13. Repeatedly frozen and thawed rat liver tissue failed to induce visible lysis while living tissue from the same rat caused appreciable lysis; collagenolytic activity was inhibited by addition of sodium EDTA to a final concentration of 0.01 M (manuscript in preparation). Neither aerobic nor anaerobic bacterial contamination was detected in gels where lysis was seen.

Thus the increased collagenolytic activity observed in experimental hepatic fibrosis must be due to collagenase. The proliferation of collagen fibres must be because collagen is synthesised more rapidly than it is resorbed. The discontinuation of toxic stimuli presumably results in increased collagenolytic activity to resorb the excessive collagen fibres. The mechanism of hepatic fibrogenesis in human beings may be more complicated; we shall investigate it from the viewpoint of collagen metabolism in the liver.

## Glutamate metabolism in the frog retina

THE existence of a compartmented metabolism of glutamate in cerebral cortex is well established1.2. When, for example, glutamate, acetate or y-aminobutyric acid (GA) are metabolised by the tissue the specific activity of the glutamine formed exceeds that of the total tissue glutamate pool. As the immediate precursor of glutamine is glutamate, the implication must be that there is more than one pool of the latter. A model consisting of a minimum of three compartments seems most compatible with available data and compartment 1, from which glutamine is rapidly formed, is thought to be located in glial cells1.2.

Why metabolism within the central nervous system is organised in this way is not certain but it has been proposed2 that it may relate to the role of GABA as an inhibitory neurotransmitter-the suggestion being that GABA, when released by neurones, is taken up by the glia, replacement carbon atoms then being returned to the neurones in the form of glutamine.

There is evidence that GABA may function as a neurotransmitter in the vertebrate retina<sup>3,4</sup>. Wide species differences exist however<sup>4</sup>. In particular, autoradiography has shown that, in mammalian retinae, exogenously applied GABA is accumulated into glial cells<sup>5-7</sup>; in the rabbit retina amacrine cells are also labelled<sup>7-9</sup>. In contrast, in lower order vertebrates such as goldfish, frog, pigeon and chicken, GABA goes solely into neurones<sup>10-12</sup>. There are insufficient data from which to evaluate fully the role of GABA in mammalian and other retinae but the above results imply fundamental differences in the way that the two groups handle the amino acid.

More than one pool of glutamate is present in rat retina<sup>13</sup> and, as in brain, glutamate, aspartate, acetate, GABA, leucine and bicarbonate are all effective precursors of glutamine by way of a 'small' glutamate compartment. Because of the species differences in GABA uptake into retinal tissue and the postulated connection between glutamate compartmentation and the functional organisation of GABA, we thought it of interest to know how glutamate is metabolised in the frog retina. We have therefore investigated the metabolism of labelled acetate, glutamate and glucose in this tissue and have identified the cells accumulating <sup>3</sup>H-glutamic acid by light microscope autoradiography<sup>6</sup>.

All frogs (Rana temporaria) were dark adapted overnight to free the neural retina from extensive contact with the pigment epithelium. The retinae were then dissected out<sup>12</sup> under normal room lighting and incubated in 20 ml specimen bottles. At the end of the incubation period the labelled amino acids were extracted from the tissue and processed by•a modification of the method described by Starr<sup>13</sup>. The concentrations of the amino acids present in the retina, after control incubations in the presence of unlabelled substrate, were determined using double label dansylation<sup>14,15</sup>.

The results are detailed in Table 1. With glutamate or acetate as substrate, the specific activity (RSA) of glutamine relative to glutamate, after 30 min in vitro incubation, was greater than unity. In contrast, when glucose was the substrate, a normal precursor/product relationship was observed and the RSA was less than one. Thus a compartmentation of glutamate metabolism, qualitatively similar to that in the rat retina<sup>13</sup>, is present in the frog retina also. In addition the results imply that, as in other areas of the CNS, glutamate produced from glucose passes into the glutamate pool(s) from which glutamine is formed.

Table 1 Formation of aspartate, glutamate, glutamine and GABA from labelled precursors

Amino	C-glucose		1-14 C-acetate		U-14 C-glutamate		nmol per retina	
acid	SA	RSA	SA	RSA	SA	RSA	$\pm$ s.e.m. $16.6\pm2.1$ $40.4\pm0.7$ $23.7\pm1.0$ $28.6\pm0.6$	
Aspartate	58.3	0.28	67.6	0.29	369	0.13		
Glutamate	205	1.0	231	1.0	2757	1.0		
Glutamine	135	0.66	372	1.61	8952	3.25		
GABA	159	0.77	94	0.40	495	0.18		

Retinae were preincubated for 15 min at 25° C in 2 ml oxygenated bicarbonate Ringer<sup>13</sup> containing 50 mg % glucose and then incubated for 30 min in the presence of p-U-<sup>13</sup>C-glucose (2.5 µCi ml<sup>-1</sup>; 268 mCi mmol<sup>-1</sup>), 1-<sup>14</sup>C-sodium acetate (6.7 µCi ml<sup>-1</sup>; 56 mCi mmol<sup>-1</sup>) or L-U-<sup>13</sup>C-glutamic acid (2 µCi ml<sup>-1</sup>; 260 mCi mmol<sup>-1</sup>). After washing, free amino acids were isolated from the retinae and the extracts were evaporated to dryness, taken up in 100 µl water and 30 µl taken for separation on Whatman No. 1 chromatography sheets (descending)<sup>13</sup>. The solvent was saturated aqueous phenol. The amino acids were separately eluted with 1.0 ml water and the radioactivity estimated by liquid scintillation counting<sup>12</sup>. Standard quantities of glutamate, aspartate, glutamine and GABA, added to retinal homogenates, were processed and recoveries of 67-95% obtained. Experimental values were corrected accordingly. Endogenous amino acids were estimated by double label dansylation as previously described<sup>15</sup>.

SA denotes d.p.m. per µmol amino acid × 10<sup>-3</sup> and RSA the specific activity relative to glutamate.

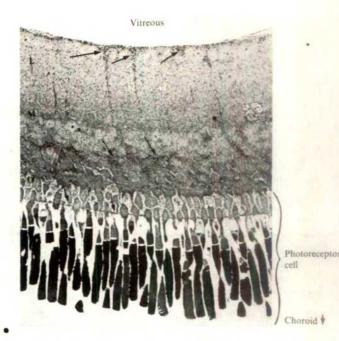

Fig. 1 Light microscope autoradiograph of frog retina showing the incorporation of <sup>3</sup>H-glutamic acid into all regions of the Müller (glial) cells. Activity can be seen over the terminal expansions of these fibres at the inner limiting membrane (L), over their cell bodies (M) and over the outer limiting membrane (O)—the proximal termination of the Müller cell (×577.50). Retinae were incubated for 30 min in the presence of 100 µCi ml<sup>-1</sup> Dt.-2-<sup>3</sup>H-glutamic acid (1.4 Ci mmol<sup>-1</sup>) at 25° C. They were then fixed in glutaraldehyde followed by osmium tetroxide and processed for autoradiography. Ilford L4 photographic emulsion was used for the autoradiography and the slides exposed for 3 d.

A representative autoradiograph obtained from a frog retina preloaded with <sup>3</sup>H glutamic acid (Fig. 1) shows there is a preferential accumulation by the Müller (glial) cells. Glutamate is also taken up by glia in both the rabbit <sup>9</sup> and rat retina (Neal and White, personal communication). In our present study, with glutamate as substrate, labelled glutamine constituted 50% of the tissue radioactivity and it would seem, therefore, that these cells are the site of a glutamate pool that produces glutamine, certainly when glutamate is used as the labelled precursor. In current terminology this would correspond to the small glutamate compartment which in brain, as well, is thought to be located in the glial cells<sup>1,2</sup>.

The formation of glutamine from glutamate within the Müller cells is compatible with the GABA-glutamine cycle proposed by Van den Berg<sup>2</sup>. This cycle might occur in the rat retina where exogenous <sup>3</sup>H-GABA is taken up by glial cells<sup>5</sup>. Such a scheme is, however, difficult to reconcile with the neuronal incorporation of <sup>3</sup>H-GABA in the frog retina<sup>12</sup>.

A.J.K. is in receipt of a Research Training Scholarship from the Wellcome Trust and financial support was received from the Medical Research Council. We thank Miss P. Aldred and Mr P. Ansell for technical assistance with the autoradiography.

## Activity of CNS depressants related to hydrophobicity

SEVERAL theories of general anaesthesia account for the depression of neuronal excitability as a depression of membrane mechanisms underlying axonal conduction1-4 or synaptic transmission<sup>5-16</sup>. The latter is more likely since general anaesthetics depress transmission in concentrations which do not block axonal conduction<sup>6,7,11,15,18</sup>. In vertebrates, excitatory postsynaptic potentials (epsps) are invariably depressed 12,15-20, while under the same conditions inhibitory postsynaptic potentials (ipsps)4.21-23 and excitatory presynaptic potentials (resulting in presynaptic inhibition) are preserved (and prolonged)<sup>24-27</sup>. Using invertebrate preparations we found<sup>28</sup> that (1) pentobarbital selectively and reversibly depresses Na+-dependent epsps without affecting either Cl<sup>-</sup>- or K<sup>+</sup>dependent ipsps, and (2) pentobarbital and other central nervous system (CNS) depressants selectively and reversibly depress postsynaptic excitation (induced by application of putative transmitters) which is coupled primarily to an increase in Na+ conductance without affecting postsynaptic inhibition (induced by application of putative transmitters) which is coupled to either Cl<sup>-</sup> or K<sup>+</sup> conductance increases. Selective depression of postsynaptic excitation would presumably lead to a decrease in the ratio of epsps to ipsps and thus account for much of the generalised decrease in neuronal activity during general anaesthesia. The observations by Meyer29 and Overton30 that general anaesthetic potency is directly proportional to the oil/water partition coefficient have prompted me to investigate the correlation between depressant activity and hydrophobicity. I report here that (1) depressant activity on invertebrate postsynaptic membranes is quantitatively correlated with hydrophobicity (r=0.982), and (2) analysis of published data from a vertebrate preparation indicates that the ratio of drug concentrations depressing axonal conduction and synaptic transmission equally is also quantitatively correlated with hydrophobicity (r = 0.96).

Dose-response curves of the inhibitory effect of six CNS depressants (chloroform, chloralose, diphenylhydantoin-DPH, ethanol, pentobarbital and urethane) on the postsynaptic voltage response and conductance change of an identified neurone in Otala lactea in response to addition of 10<sup>-5</sup> M acetylcholine (ACh) were constructed. The ACh response has an inversion potential of 0 to +10 mV and is dependent primarily on Na+ and secondarily on K+ (my unpublished observations). The dose-response curves approximately paralleled one another, suggesting that the agents each affected the ACh response through similar mechanisms. At least three and as many as ten curves were used to establish the concentration of an agent which inhibited the ACh response by 50%. The concentration producing 50% inhibition can be correlated quantitatively with the agent's hydrophobicity, as reflected by its octanol/water partition coefficient (Table 1, Fig. 1). Least

Hydrophobicity and concentration of CNS depressant Table 1 inhibiting ACh response on a molluscan neurone

Compound	log P*	Observed	log 1/C Calculated	Dev.
Ethanol	-0.32	0.70	0.85	+0.15
Urethane	-0.15†	1.23	1.04	-0.19
Chloralose	1.60	3.00	3.09	+0.09
Chloroform	2.00	3.16	3.56	+0.50
Pentobarbital	2.00	4.00	3.56	-0.44
Diphenlyhydantoin	2.50	4.16	4.15	0.01

octanol/water partition coefficient; C, molar concentration.

P, octanoi/water == \*Obtained from ref. 47. † Experimentally determined by C. Silipo and C. Hansch.

squares analysis of my data yielded equation (1) which relates the molar concentration, C, causing 50% depression of the ACh response to octanol/water partition coefficient, P

$$\log 1/C = 1.17 \log P + 1.22 \tag{1}$$

A statistical analysis, using F tests, gave:

$$\frac{n}{6} \frac{r}{0.982} \frac{s}{0.295} \frac{F_{\text{ratio}}}{F_{1,4} = 125; F_{\alpha} = 0.0005} = 106$$

where n is the number of data points, r is the correlation coefficient, s is the standard error of the estimate,  $F_{\text{ratio}}$  for significance test with  $F_{k, n-k-i}$  compared with that at a specific level of confidence,  $\alpha$ , where k is the number of independent variables and n is the number of data points used. Thus depressant activity is positively and significantly correlated with hydrophobicity over a thousandfold range of hydrophobicity and activity for the differently structured compounds, implying that steric requirements for activity are minimal.

This depression of postsynaptic excitation in invertebrates complements similar observations in the vertebrate at neuromuscular junctions<sup>1,12,31-33</sup> and on CNS neurones<sup>34-38</sup>. An increase in evoked transmitter release at neuromuscular junctions during exposure to barbiturates19,20 when epsp amplitude is reduced indicates that epsp depression here is due to a postsynaptic action. Generalised depression of postsynaptic excitation coupled primarily to Na+ (and secondarily to K+) conductance may thus account for much of the depression of neuronal excitability. Since, however, blockage of axonal conduction has been described in both invertebrates and vertebrates1-4,39, I have investigated its importance by analysing data published by Larrabee and Posternak<sup>6</sup>. They examined

the effects of general anaesthetics on axonal conduction and synaptic transmission through the cat stellate ganglion. The concentration blocking the postsynaptic event by 50% correlated with hydrophobicity and least squares and statistical analysis of the data yield

$$\log 1/C = 1.21 \log P + 0.83 \tag{2}$$

and a correlation coefficient, r = 0.96. Equation (2) is close to that found in an analysis of data from the rabbit cervical ganglion40 by Hansch and Dunn41 who obtained

$$\log 1/C = 1.11 \log P + 0.81 \tag{3}$$

and r = 0.978. Equations (2) and (3), calculated using data from vertebrate synapses, are similar to equation (1), the major difference lying in the intercepts, which reflect the sensitivities of both the systems to the drugs and of the drug effects to the assay. The similarity inslopes of the equations indicates a similar dependency of activity on hydrophobicity.

The concentration required to block the synaptically-derived compound action potential was compared with the concentration required to block the directly recorded (presynaptic) compound action potential by an equal percentage. The ratio of the concentrations, R, was then correlated with hydrophobicity, P (data in Table 2):

$$\log R = 0.49 \log P - 0.03 \tag{4}$$

A statistical analysis gave

$$\frac{n}{6} \frac{r}{0.96} \frac{s}{0.295} \frac{F_{\text{ratio}}}{F_{1,4} = 262; F_{\alpha} = \frac{\bullet}{0000.5} = 106}$$

Equation (4) allows one to predict the ratio of depression of synaptic transmission to depression of axonal conduction from hydrophobicity. Pentobarbital, chloroform and chloretone are about ten times and ether about three times more selective for blocking synaptic transmission than for blocking axonal conduction, while ethanol and urethane appear to depress both aspects of neuronal excitation equally. Possible mechanisms include (1) a decrease in transmitter release; (2) a decreased chemosensitivity of postsynaptic receptor; (3) a blockade of the conductance mechanism coupled to the receptor, and (4) a nonspecific alteration in postsynaptic membrane properties so as to decrease the probability of excitation occurring. An increase in transmitter release at vertebrate neuromuscular junctions by these agents has been reported19,20,42 in contrast to a decrease in release at motoneurones<sup>43</sup>. (The latter may be due to an increase in presynaptic inhibition through effects on the primary afferent fibre terminals.) Nonspecific alterations in postsynaptic membrane properties do occur13,14 but at 10-100 times the concentration necessary to selectively block the receptor-coupled conductance mechanism in invertebrates and to produce effective general anaesthesia44. If the blockade of synaptic transmission in this ganglionic preparation is related to the postsynaptic effects observed in invertebrate systems<sup>28</sup> and in vertebrate neuromuscular junctions 19, 20 where alterations in end-plate currents by general anaesthetics have been described45,46, then depression of synaptic physiology in vertebrate

Table 2 Hydrophobicity and ratio of CNS depressant concentration inhibiting pre- and postsynaptic compound action potential

Compound	log P*	Observedt	log Ratio Calculated	Dev.
Ethanol	-0.32	0.30	-0.19	-0.11
Urethane	-0.15	-0.10	-0.10	0.11

ganglia more likely reflects a depression of the conductance mechanism coupled to postsynaptic receptors.

In summary, analysis of data derived from invertebrate and vertebrate preparations indicates that (1) agents which depress CNS excitability selectively depress epsps in invertebrates which are predominantly Na+ dependent; (2) depressant activity at a molluscan postsynaptic membrane is correlated with hydrophobicity (r = 0.982); (3) depression of a postsynaptically derived compound action potential is similarly correlated with hydrophobicity (r = 0.96, 0.978); and (4) the ratio of drug concentrations required to depress postsynaptic excitation and presynaptic axonal conduction equally is also positively correlated with hydrophobicity (r = 0.96). The results suggest that much of the depression of CNS excitability observed with those agents commonly used as general anaesthetics is due primarily to a selective depression of postsynaptic excitation through a postsynaptic mechanism and secondarily to a depression of axonal conduction by the more hydrophilic agents (ethanol and urethane). In addition, the mechanisms underlying the effects of general anaesthetics on presynaptic physiology in the vertebrate and the relative importance of presynaptic inhibition in the depression of CNS excitability by these agents requires further investigation. Finally, the roles played by hydrophobicity in determining whether the attack of these agents is directed either to voltage-independent (postsynaptic receptor-coupled) and/or to voltage-dependent (axonal) monovalent conductance mechanisms (and to presynaptic physiology) remains to be elucidated.

## Temperature-dependent interconversion of histamine H<sub>1</sub> and H<sub>2</sub> receptors in guinea pig ileum

HISTAMINE receptors mediating changes in gastric secretion are resistant to blockade by most antihistamines1, and this led Ash and Schild' to propose two classes of receptors, H typified by the system in guinea pig ileum or bronchi, and H<sub>2</sub> responsible for effects on atria and gastric secretion. This concept is supported by the demonstration that, in contrast to most antihistamines, a series of substituted imidazole compounds are competitive antagonists of the H2 receptor with negligible action on H1 (refs 3, 4).

During studies of the effects of changes in temperature on the blocking action of some competitive H1 antagonists, we found that below 18° C promethazine ceased to be competitive and appeared to act non-competitively. Since promethazine can act as a non-competitive antagonist of the H<sub>2</sub> receptor in atria<sup>5</sup> this raised the possibility of some transformation of the H1 to the H2 receptor at lower temperatures. We report here studies which support this view.

Isolated strips of the longitudinal smooth muscle of guinea pig ileum6 were set up in organ baths containing

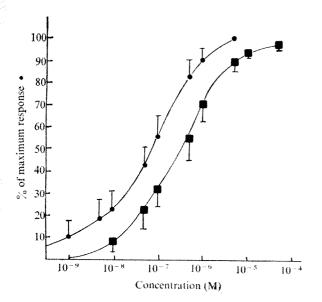

Fig. 1 Dose-response curves for histamine at 12° C. Bars represent standard error from five experiments.  $\bullet$ , Control;  $\bullet$ , after treatment with  $7.5 \times 10^{-3}$  M metiamide.

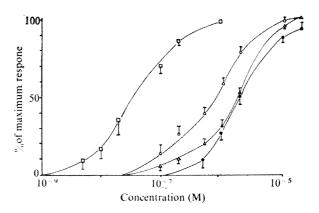

Fig. 2 Dose-response curves for histamine. Bars represent standard errors from six experiments. □, Control response to histamine at 37° C; △, after  $5 \times 10^{-8}$  M tripelennamine at 37° C; O, after  $5 \times 10^{-8}$  M tripelennamine at 12° C; •, after  $5 \times 10^{-8}$  M tripelennamine and  $7.5 \times 10^{-5}$  M metiamide at 12° C.

Tyrode solution gassed with 95% O2:5% CO2 and allowed to equilibrate for 1 h at 37° C. Contractions were recorded using either a frontal writing lever and a kymograph, or a linear motion transducer (Hewlett Packard 7DCDT) and a polygraph (Grass 5P1). Responses to histamine in this preparation were stable for several hours both at 37° C and 12°C, although some changes in shape of the doseresponse curve were observed at lower temperatures. At 37° C the H<sub>2</sub> antagonist metiamide, at concentrations up to  $2 \times 10^{-4}$  M, had no effect on the responses to histamine, in agreement with the findings of Black et al.4. At 12° C  $7.5 \times 10^{-3}$  M metiamide produced a parallel shift in doseresponse curve to the right (Fig. 1). Rewarming the tissue to 37° C resulted in some persistence of blockade, but after 1 h responses were similar to those obtained initially in the absence of metiamide.

To demonstrate that the effects were specific for the histamine receptor these experiments were repeated using acetylcholine as the agonist. Metiamide produced no antagonish of the responses to this agent at either 37° C or 12° C at concentrations up to 10<sup>-4</sup> M.

The H<sub>1</sub> receptor antagonists usually have some action on H<sub>2</sub> receptors, but tripelennamine is reported to have very high selectivity for  $H_1$  (ref. 7). Tissues treated with  $5 \times 10^{-8}$ M tripelennamine at 37° C showed the expected shift in doseresponse curve to the right. At 12° C, and in the continued presence of tripelennamine, some reversal of blockade occurred and this could be blocked again with metiamide (Fig. 2). As this recovery was unaffected by 10<sup>-6</sup> M atropine it is unlikely to have arisen from any action of histamine on release of acetylcholine. No sensitisation to acetylcholine was observed at lower temperatures, after treatment with either atropine or tripelennamine.

The ability of metiamide to antagonise the histamineinduced responses of this preparation at lower temperatures and the reduced ability of tripelennamine to block contractions under these circumstances suggests that at 12° C some receptors were transformed from H<sub>1</sub> to H<sub>2</sub>. This is in many ways similar to the findings of Kunos et al.\* concerning the interconversion of the  $\alpha$  and  $\beta$  receptors in heart, but we are unable, to present, as they did, evidence based on selective actions of agonists since selective H<sub>1</sub> and H<sub>2</sub> agonists were not available to us. Betazole is reported to be about ten times as active on sites regarded as H<sub>2</sub> receptors, and it would thus be expected that the tissue would show increased sensitivity to betazole at lower temperatures. A small increase in sensitivity to betazole was observed in three of six experiments and this was antagonised with metiamide, but control experiments indicated that betazole shows marked tachyphylaxis particularly at

low temperatures, and this observation makes study of the H<sub>1</sub> to H<sub>2</sub> interconversion using this agonist difficult to evaluate.

In conclusion, our data suggest that at low temperatures some H1 receptors of guinea pig ileum convert to a form similar to the H<sub>2</sub> receptor. The concept of a change in the properties of receptors as a result of changes in temperature is not unexpected in view of the concept of membrane phase transitions supported by enzyme studies10. Furthermore, Rocha e Silvaii has suggested that the properties of the histamine receptor at temperatures above 20° C are different from those at lower temperatures.

We thank the Medical Research Council of Canada for financial support and our colleagues in this department for advice and comments.

### Astrocyte-specific protein and radial glia in the cerebral cortex of newborn rat

Here we show that radial glia directing neuronal migration in the cerebral cortex during development can respond to injury with the production of a protein specific to astrocytes, and may thus be regarded as an early form of the mature astrocyte.

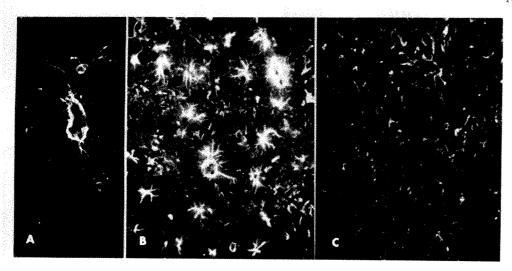

The migration of nerve cells from their site of origin in germinal zones to their final destination is a general rule in brain development, the granular layer of the hippocampus being the only possible exception. Migrating neuroblasts in the cerebellar and cerebral hemispheres are in close contact with radially oriented glial processes1-3. Such close relationship suggests that glia play a role in directing radial migration of neurones through complex regions of the brain which contain bundles of nerve fibres in various orientations early in development. In the cerebellum, Bergmann glia provide the guidelines for neurones migrating inwards from the external granular layer. They persist in adult life as a distinct form of fibrous astrocytes with straight parallel processes crossing the molecular layer at right angles and reaching the surface of the cerebellum4. During development of the cerebral hemispheres the radially oriented glial cells directing the outward migration of neurones from the ventricular zone have been observed in many species by the Golgi method and more recently by electron microscopy in the monkey and the rat2,3. These cells are not observed in mature brain and have been interpreted as spongioblasts (pluripotential glial precursors3), or as transient forms of astroglia transforming into astrocytes of more typical appearance later in development<sup>2.5</sup>.

The glial fibrillary acidic (GFA) protein is brain specific but not species specific and is selectively located in fibrous astrocytes<sup>6,7</sup>. The appearance and distribution of neuroglia using immunofluorescence with GFA protein antibodies correspond to those described by Weigert4 with his method for fibrous astrocytes. By immunofluorescence, Bergmann gliai processes transversing the external granular layer and molecular layer of the cerebellum are first demonstrated on the third postnatal day in the rat and mouse, thus before the beginning of neuronal migration in these species<sup>8.9</sup>. In a similar study of astroglial differentiation in the rat cerebral hemipheres', radial glial processes were only demonstrated in the granular layer of the hippocampus in the first weeks of postnatal development. Immunofluorescent fibres were first observed on the 18th embryonic day in the medial wall of the lateral ventricles and they had no radial orientation.

After injury the astrocytes become larger with increasing gliofibrillary content. In a study of the glial reaction during development, the brains of adult and newborn rats were stabbed unilaterally in the lateral frontal region. This was done with a scalpel through the intact skull in the parasaggital plane. Animals were killed at intervals ranging from 2 d up to 2 months. Air-dried coronal cryostat sections were used for immunofluorescence studies. Adjacent sections were stained with toluidine blue. GFA protein antisera previously obtained from New Zealand albino rabbits7 were used. The rabbits had been injected with human GFA protein purified from multiple sclerosis plaques, a severely gliosed tissue markedly enriched in GFA protein<sup>10,11</sup>. The immunofluorescence test was carried out according to Coons indirect procedure, as previously described7. Control sections were incubated with preimmunisation sera and immune sera absorbed with GFA protein. GFA protein antisera and preimmunisation sera were used in 1/50 dilutions. At this titre essentially no fluorescein staining was seen in control sections. The fluorescein-labelled goat anti-rabbit globulin serum was used in 1/10 dilutions.

In toluidine blue stained sections the damage to the lateral frontal cortex was extremely limited and confined to the vicinity of the blade track. In the subjacent white matter the damage was more extensive and in newborn animals resulted in a necrotic and cavitating lesion bordering the frontal cortex on the medial surface of the hemisphere.

The astrocytic reaction to injury was studied by immunofluorescence with GFA protein antiserum in the frontal cortex. In the rat isocortex most astrocytes are protoplasmic and do not contain GFA protein in detectable amounts. In the adult animal immunofluorescence is essentially confined to the external glial membrane on the surface of the brain and to the glial membranes surrounding small arteries and veins (Fig. 1A). None of these structures is immunofluorescent in the newborn rat. A continuous external glial membrane is first observed by immunofluorescence on the 9th day, while the perivascular glial membranes form later (9-18 d) (ref. 7). In the adult rat 2 d after stabbing protoplasmic astrocytes had switched to GFA protein production and thus became brightly immunofluorescent with GFA protein antiserum (Fig. 1B). This change, still present 2 months after injury, was not confined to the vicinity of the wound but extended through wide areas of the cortex in the stabbed hemisphere. In newborn rats sacrificed 2 d after stabbing, at a time when no immunofluorescence is normally present, immunofluorescent fibres had appeared around the blade track in the lateral frontal cortex (Fig. 1C) and in the medial frontal cortex overlying the necrotic lesion in the white matter (Fig. 2). While in the lateral cortex these processes were irregularly oriented. in the medial cortex they had the appearance of thin parallel processes transversing the cortex at right angles to the surface. These radial processes had disappeared 13 d after injury. At that time immunofluorescent fibres had the same irregular orientation in the medial and lateral cortex. In 1-month-old

Astrocytic response to injury in the middle layers of the rat frontal cortex 2 d after stabbing. In the normal adult rat (A) immunofluorescence with GFA protein antiserum is essentially confined to the glial membranes surrounding small arteries and veins. After stabbing (B) the protoplasmic astrocytes which normally do not stain become brightly immunofluorescent. This is an extensive reaction involving large areas of the stabbed hemisphere. In the newborn rat (C) the reaction is already present but less intense (no immunofluorescence is normally seen (×14.5) at this stage of development). Immunofluorescence with GFA protein antiserum.

animals which had been stabbed at birth, the reactive astrocytes in the cerebral cortex were identical to those observed in mature animals following the same type of lesion, that is they appeared as conventional astrocytes in Cajal preparations. The astrocytic. reaction had become very extensive and was also present in the cortex of the unstabbed hemisphere.

Radial glial cells in the medial frontal cortex of the newborn rat behave like protoplasmic astrocytes in mature brain. that is, they are switched to GFA protein production as a response to injury. Radial glia may thus be considered as an · early form of astrocytes that transforms into astrocytes of more conventional morphology in the first weeks of postnatal development. It may be noted that radial glia persist through adult life as the main type of supporting glia in lower vertebrates12. As is the case with astrocytes in mammalian brain, radial glial cells in lower vertebrates may not contain GFA protein in detectable amounts. Thus, radial glia could be demonstrated by immunofluorescence in the optic tectum of the turtle, but not in the optic tectum of the goldfish and frog6.

It seems that astrocytic determination, as opposed to GFA protein expression, is an early phenomenon in development. According to Rakic (personal communication), some of the elongated columnar neuroepithelial cells spanning the entire thickness of the telencephalic wall, develop vascular attachments as early as 48 d after conception in the monkey (gestation time 165 d). The constraints imposed by the mesenchymal interaction are probably a major factor restricting the pluripotential neuroepithelium to the role of supporting glia (radial astrocytes). GFA protein expression occurs much later in the

Fig. 2 Radial glia in the newborn rat (deep layers of the medial frontal cortex) 2 d after stabbing. Radial glia is not stained by immunofluorescence with GFA protein antiserum in normal development. W, injured white matter underlying the medial frontal cortex. Immunofluorescence with GFA protein antiserum

course of normal development, most likely as a result of permissive tissue interactions.

## Apomorphine and morphine stimulate prostaglandin biosynthesis

Among the acute pharmacological effects of apomorphine and morphine are emesis, hyperthermia and hyperglycaemia1,2, Because administration of prostaglandins also elicits each of these effects3-10, we have investigated whether apomorphine or morphine stimulates prostaglandin biosynthesis. Here we describe experiments showing that both drugs stimulate, although possibly in a somewhat different way, the prostaglandin (PG) synthetase of bull seminal vesicles.

Bull seminal vesicles, kept for not more than four weeks at -20° C, were homogenised for 1-2 min at 4° C in three volumes of 50 mM phosphate buffer (pH 7.4) containing 1 mM EDTA. The strained homogenate was centrifuged at 600g for 15 min and the supernatant separated and stored under nitrogen at  $-20^{\circ}$  C. Two different preparations of this supernatant were used in the course of these experiments, with comparable results. The incubation mixture consisted of 500 µl of the supernatant in 2 ml of 50 mM phosphate buffer, with or without apomorphine hydrochloride or morphine sulphate. The reaction was started by addition of sodium arachidonate (final concentration 61 µM) and the tubes were

aerated with gentle shaking. After 15 min, the reaction was stopped by adding 2 ml 0.2 M citric acid and the mixture was extracted with 16 ml ethylacetate. After centrifugation at 600g for 5 min, 11 ml of the ethylacetate layer was evaporated to dryness in vacuo, the residue dissolved in 500 µl ethanol, and 100 µl aliquots were diluted 50-fold in Krebs' solution. Volumes of not more than 0.25 ml of these aqueous ethanol extracts were assayed against reference PGE2 on rat isolated stomach fundus strip, superfused at 5 ml min-1 with Krebs' solution, containing mixed antagonists of acetylcholine, catecholamines, histamine and 5-hydroxytryptamine<sup>11</sup>, and aerated with oxygen containing 5% carbon dioxide.

In some experiments, aliquots (125 µl) of the ethanol solution were chromatographed in the A I system<sup>12</sup> on silica gel plates with PGE2 and PGF20 markers. The areas corresponding to each prostaglandin were separately extracted with ethanol and the residues after evaporation were redissolved in 200  $\mu$ l ethanol and diluted 25-fold with water for bioassay. Assays were then performed against reference PGE, and PGF, on rat isolated fundus strip and colon, superfused in series. The concentrations of drugs are expressed as those of active acid

In control experiments, we found that addition of apomorphine (100 or 400  $\mu g$  ml  $^{-1})$  or morphine (10 or 100  $\mu g$  ml  $^{-1})$   $_{\bullet}$ to the boiled enzyme before incubation did not affect the blank assay values for total prostaglandin, indicating that the assay was not affected by drug being carried through the extraction process. In other control experiments, 3H-PGE2 and 3H-PGF2a were incubated with unboiled or boiled enzyme for 15 min, extracted, separated by thin layer chromatography, and assayed. In this procedure, <8% of the PGE<sub>1</sub> and no PGF<sub>2</sub> $\alpha$ were lost during incubation with unboiled enzyme preparation. We concluded that a very large part of the increases in net production of prostaglandins found in the presence of apomorphine or morphine could be attributed to increased prostaglandin biosynthesis and not to protection of prostaglandin from enzymatic breakdown.

PG synthetase was incubated with arachidonic acid in the absence of drug, or in the presence of different concentrations of apomorphine, and the yield of prostaglandin-like material assayed against PGE. After subtracting the amount of PGlike material found in control tubes containing boiled enzyme, the assay value was taken to represent PG produced by the action of synthetase during incubation. With unboiled enzyme in the absence of drug, a mean of 1,137 ng (s.e.  $\pm$ 129) of prostaglandin was produced. When a pomorphine (0.1–100  $\mu g$ ml-1) was present, mean PG production exceeded the control value by 1.26-fold to 4.42-fold (Fig. 1). In the presence of apomorphine (1-100 µg ml<sup>-1</sup>), mean PG production sharply increased with increasing concentration of drug (slope, 1.64; s.e.,  $\pm 0.379$ , P < 0.001). A higher concentration of apomorphine (400 µg ml-1) inhibited PG production. From the mean concentration/response line it was calculated that 1.71 µg ml<sup>-1</sup> (limits, 1.33-5,44) of apomorphine were required to increase the PG production by a factor of 1.5 (SC 50).

In similar experiments, morphine (0.01-100 µg ml<sup>-1</sup>) stimulated PG production by 1.21-fold to 2.17-fold (Fig. 2). Compared with apomorphine, morphine had a concentration/ response line of low slope; but this was statistically significant (slope, 0.149; s.e.,  $\pm 0.045$ ; P < 0.005). The SC<sub>50</sub> value for morphine was 1.59  $\mu$ g ml<sup>-1</sup> (limits, 0.0855-52.4).

In both experiments with each drug, in which prostaglandins produced were separated by thin layer chromatography before assay, apomorphine and morphine stimulated production of both PGE<sub>2</sub> and PGF<sub>2a</sub>. For example, in one experiment, apomorphine, at 100 μg ml<sup>-1</sup>, increased production of PGE<sub>s</sub> by 2.47-fold and that of PGF<sub>2a</sub> by 1.66-fold; and morphine, at 1 μg mI<sup>-1</sup>, increased production of PGE<sub>2</sub> by 1.30-fold and of  $PGF_{2\alpha}$  by 1.27-fold.

In three independent experiments, chlorpromazine hydrochloride and sodium acetylsalicylate were tested for their ability to inhibit the stimulation of PG synthetase induced by

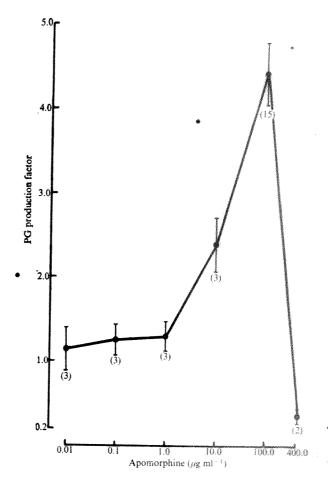

Fig. 1 Stimulation by apomorphine of the PG synthetase of built seminal vesicles. The production factor is the factor by which prostaglandin production in the presence of apomorphine exceeded that in its absence in reference tubes in the same experiment. The results of 2-15 independent experiments are expressed as the mean production factor  $\pm$  s.e. In brackets, the number of values used to calculate each mean

100 µg ml<sup>-1</sup> of apomorphine. Chlorpromazine, at 0.9, 9 and 90 μg ml<sup>-1</sup>, reduced apomorphine stimulation in a dose-related way, by mean percentages of 3.1, 25.8 and 60.5 respectively. Acetylsalicylate reduced PG production both in the presence and absence of apomorphine.

These experiments show that apomorphine and morphine stimulate the prostaglandin synthetase of bull seminal vesicles in the absence of the cofactors, glutathione and hydroquinone, that are usually added. Experiments now in progress show that such stimulation can also occur in the presence of these cofactors<sup>13</sup>. Other experiments in progress show that the stimulation by apomorphine and morphine of PG synthetase is not restricted to the enzyme from bull seminal vesicles, but occurs also with synthetase from rabbit brain14.

The low slope of the concentration/response relationship for morphine could arise from various causes; for example, the action of morphine could be limited by a factor independent of the drug concentration; or, again, morphine might activate processes with opposed concentration/response relationships. The difference in this respect from apomorphine may indicate a difference in the mechanism of action of morphine and apomorphine on this preparation.

Morphine is known to act centrally in producing emesis 16,18, hyperthermia<sup>17</sup> and hyperglycaemia<sup>18,19</sup>. Apomorphine, too, exerts these effects by acting on the brain (ref. 15 and W. Feldberg, unpublished). In all the experiments reported above, apomorphine and morphine stimulated prostaglandin biosynthesis at concentrations less than those attainable in the brain with tolerated doses of either drug<sup>20,21</sup>. Prostaglandins are produced in the brain<sup>22</sup>, and E-type prostaglandins are known to act there to elicit fever 7.8. It is not known, however,

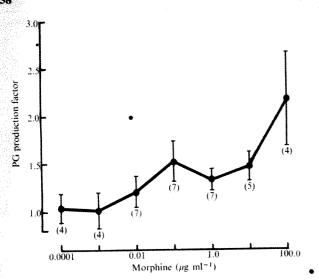

Fig. 2 Stimulation by morphine of the PG synthetase of bull seminal vesicles. Values are the means of 4-7 independent experiments. Other details as in Fig. 1.

whether prostaglandins can elicit vomiting or hyperglycaemia also by a central action. We therefore propose that the hyperthermic effects of apomorphine and morphine, and possibly also their emetic, hyperglycaemic and allied effects, may be due to the stimulation of prostaglandin biosynthesis. This proposition requires that chlorpromazine, which inhibits apomorphine-induced vomiting in the dog23,24, should inhibit the stimulation by apomorphine of PG synthetase; and we have found this to be so.

It has recently been proposed that morphine may exert its analgesic or allied effects by inhibiting the stimulation by E prostaglandin of cyclic AMP formation<sup>25</sup>. Thus, diverse interactions with prostaglandin mechanisms might explain some depressant and excitatory effects of morphine on the nervous system and provide the basis for a mechanism of tolerance/ dependence.

We thank Miss J. Bennett, Miss A. A. Butt, Miss J. L. Copas and Miss S. M. Neal for experimental help and Mr L. C. Dinneen for statistical analysis.

## Inhibition of glycoprotein and glycolipid synthesis in hamster embryo cells by cytosine arabinoside and hydroxyurea

THE nucleoside, 1-β-D-arabinofuranosylcytosine (ara-C) and the unrelated compound, hydroxyurea, are known to inhibit DNA replication in bacterial and animal cells1-3. Arabinofuranosyl cytidine-5'-triphosphate (ara-CTP) specifically interferes with the action of DNA polymerase II in bacterial cell extracts4, whereas hydroxyurea affects the ribohucleoside diphosphate reductase reaction5. We have shown that ara-C and hydroxyurea bring about transformation of hamster embryo cells in tissue culture. Further, it has also been demonstrated that ara-C inhibits the incorporation of 3H-D-glucosamine (a precursor of N-acetylneuraminic acid) into glycoproteins and glycolipids of hamster embryo fibroblasts and transformed cells7. In continuing these experiments we have been interested in, first, determining the site or sites of action of ara-C (presumably as its triphosphate) in the cell and second, studying other inhibitors of DNA replication as to their possible effect on glycoprotein and glycolipid synthesis.

To compare the effect of ara-C and other chemicals on both DNA replication and glycoprotein/glycolipid synthesis, either secondary cultures of hamster embryo fibroblasts or transformed hamster embryo cells were used as the test system6. Cells were exposed to the different chemicals for 24 h, and the incorporation of 14C-thymidine and <sup>3</sup>H-p-glucosamine measured into acid-precipitable material at selected times during this period.

As expected, ara-C and hydroxyurea are potent inhibitors of DNA replication, while FUdR and the carcinogenic hydrocarbons were less effective in this respect (Table 1). With regard to the incorporation of 3H-D-glucosamine (glycoproteins and glycolipids), ara-C inhibited by 86% in normal cells and 50% in transformed cells (Table 1). Higher inhibitions have been observed with transformed cells in further experiments. Hydroxyurea brought about a 70% inhibition of incorporation in normal cells and a  $75\,\%$ inhibition in transformed cells, FUdR and the polycyclic hydrocarbons inhibited incorporation but to a much lesser extent (20-30%). Figure 1 shows the time curve of incorporation of 14C-thymidine (Fig. 1a) and 3H-D-glucosamine (Fig. 1b) into DNA and glycoproteins/glycolipids of trans-

## **Gas Analysis Instrumentation**

Anthony Verdin

The detection and analysis of gases and vapours has become essential in many areas of modern life; noticeably industrial safety and control of the environment. As a result a whole class of physio-chemical methods has come into existence. The author draws on his fourteen years of experience in the field to supply the only wide-ranging view of all types of equipment presently available. Both academics and industrialists will find it indispensable.

## **Electrical Breakdown in Gases**

Edited by J. A. Rees

The electrical breakdown of gases has been studied in the laboratory since before the start of this century and it is sixty years since Sir J. S. Townsend wrote his monograph *The Theory and Ionisation of Cases by Collision*. In that time the subject has been widely studied and a great deal of progress has been made in understanding many aspects of the problem. J. A. Rees has selected the major papers in this field and has linked them with comments and an introduction. Reprinted from the the original sources, the papers together provide a unique introduction to the ionisation of gases.

## Introduction to Space Charge Electron Optics

G. A. Nagy and M. Szilagyi

This introduction to space charge electron optics is an updated translation of an original Hungarian publication which presents to the West for the first time a comprehensive survey of the vast work carried out in this field in the USSR and Eastern Europe. It is however more than just a summary of literature as it also contains the solution of many problems and so points the way to future developments.

Macmillan

## BECORD STRATICAL OF THE DISTANDES

Derek V. Ager

Based on Professor Ager's observations in many parts of the world, this book takes a new look at the earth's history as recorded in the rocks. Mingling scientific comment with academic humour he presents a series of original and controversial propositions and challenges some of the assumptions that limit the views of many stratigraphers to their own particular areas of interest. His arguments are well illustrated with diagrams and photographic plates and though primarily for geologists, this book will also be of interest to teachers of physical geography.

## BECENT EABTH HISTOBY

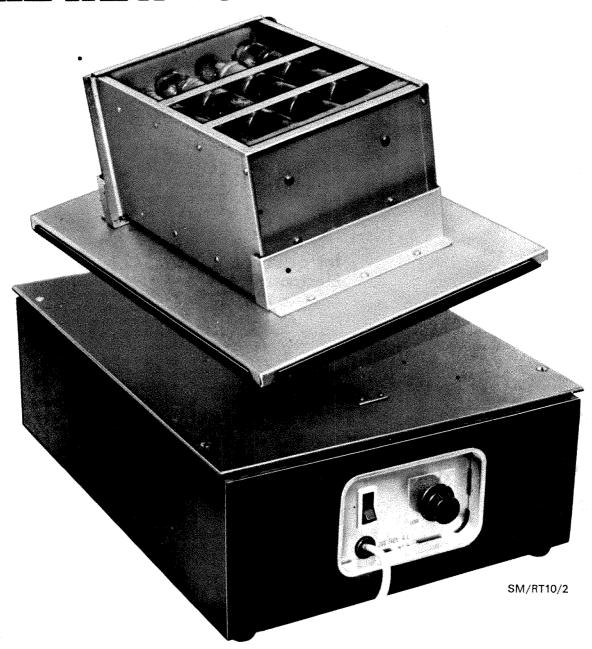

Claudio Vita-Finzi

Dr Vita-Finzi demonstrates the advantages of basing earth history on quantitative dating in its own right, rather than as an appendage of stratigraphy. Original and clearly written, the book may provoke disagreement but it is logically argued and will stimulate discussion among students and teachers.  $\mathfrak{L}3.00,$  paperback  $\mathfrak{L}1.50$ 

Macmillan

# THE NEW SUSPENSION MIXER

•The new improved Suspension Mixer provides a unique tilting-rotary action, with a variable angle of tilt from 1°–15° from the horizontal. Operation is continuous, with a variable speed range from 10–100 r.p.m. A timer up to 60 minutes and audible warning can be incorporated as an optional extra.

The principal applications are in the controlled and standardised mixing of various types of suspensions, for example—the Coombes, V.D.R.L., and many other serological and related techniques.

The variable tilting agitation with compound action for agglutination, extraction, washing, staining and photographic developments. This unit is capable of regular and continuous operation in an incubator or incubation room. It is also used in many areas of industry—pure research and Quality Control departments.

The Suspension Mixer will accommodate any one of the 'Rotatest' carrying plates and the GWB/F22 viewing lamp.

Experimental details as for Fig. 1. Incubations were at 37° C for 24 h. Four other individual experiments gave similar results.

formed cells and the effect of ara-C and hydroxyurea on these reactions. The results indicate continuous inhibition of incorporation of both radioactive precursors over 24 h.

The observations recorded in Table 1 and Fig. 1 on the simultaneous inhibition of DNA replication and glycoprotein/glycolipid synthesis by ara-C and hydroxyurea in particular, suggest some correlation between these two synthetic pathways. It is worth mentioning that ara-C (10<sup>-3</sup> M) inhibits <sup>3</sup>H-uridine incorporation by 3% (normal cells) and 11% (transformed cells) after 24 h of incubation. Protein synthesis was stimulated 3% (normal cells) and inhibited by 7% (transformed cells) at the same time period. On the other hand, hydroxyurea (10<sup>-2</sup> M) inhibited <sup>3</sup>H-uridine incorporation by 30% (normal cells) and 17% (transformed cells) after 24 h of incubation. Protein synthesis was inhibited by 12% (normal cells) and 3% (transformed cells) respectively at the same time period. Ara-C

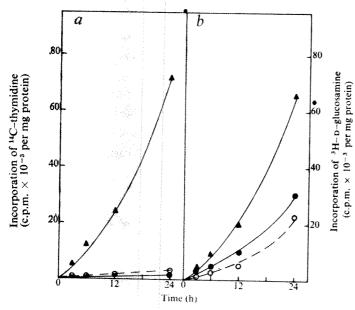

Fig. 1 Effect of ara-C and hydroxyurea on the incorporation of <sup>14</sup>C-thymidine into DNA and <sup>3</sup>H-D-glucosamine into glycoproteins and glycolipids of transformed hamster embryo cells. Incubations were carried out in Falcon Petri dishes (5.5 cm diameter) containing 5.0 × 10<sup>5</sup> cells in 3 ml of growth medium (Eagle's Minimal Essential medium containing Earles salts, 10% calf serum, penicillin and streptomycin) at 37°C in a 5% CO<sub>2</sub> atmosphere. Incorporation experiments were commenced after approximately 24 h, by which time the cells had half mono layered. Ara-C was present at a concentration of 10-<sup>3</sup> M and hydroxyurea at 10-<sup>2</sup> M. Each Petri also contained 1.0 μC <sup>14</sup>C-thymidine and 0.5 μC <sup>3</sup>H-D-glucosamine per ml incubation medium. At selected times, the medium was removed, the cells rinsed with PBS, and the cell pellet homogenised in 1 ml of water by means of a syringe using a No. 21 needle. Aliquots were taken for counting and protein determination<sup>13</sup>. For counting, samples were precipitated with cold 10% trichloroacetic acid (TCA), transferred to Whatman GF/C filters and washed with 25 ml of cold 5% TCA. Counting was carried out in a Scintillation Spectrometer. a, <sup>14</sup>C-thymidine incorporation. Δ, control; ○, ara-C; ♠, hydroxyures.

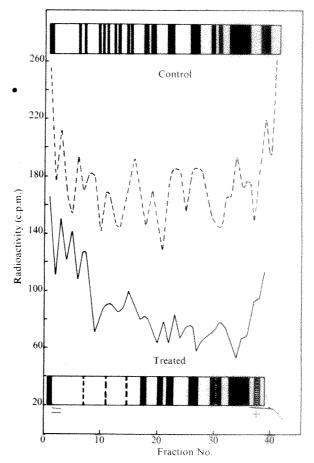

Fig. 2 Polyacrylamide gel electrophoresis of cell membrane glycoproteins. Cells were grown in Roux Flasks as described for Fig. 1. <sup>3</sup>H–D–glucosamine was present at 1.0 μCi per mi incubation medium. Ara–C when present was at a concentration of 10<sup>-3</sup> M. After 24 h at 37° C, cells were washed with PBS and removed from the glass by treatment with PBS containing 0.02% (w/v) EDTA for 30 min at 37° C. Cell membranes were isolated by a modified method based upon the procedures of Neville<sup>14</sup> and Graham<sup>15</sup>. Glucose–6–phosphatase and 5'–nucleo-tide activities were assayed according to the methods of Swanson<sup>16</sup> and Heppel and Hilmore<sup>17</sup>, respectively. Polyacrylamide gel electrophoresis was carried out in buffers according to Jones<sup>18</sup>. Protein was stained with Amido Black and gel silces were treated with H<sub>2</sub>O<sub>2</sub> before counting in Bray's solution.—Radioactivity in glycoproteins of control cells; ——, radioactivity in glycoproteins of cells treated with 10<sup>-3</sup> M ara-C.

has also been found to have no effect on the incorporation of CTP into the 3'-terminus of tRNA catalysed by the nucleotide-incorporating enzyme. The latter experiments were carried out *in vitro* with rat liver enzymes and chemically synthesised ara-CTP (T.S-B., and L. Parkin, unpublished). Further, as previously reported<sup>7</sup>, ara-C does not affect the incorporation of <sup>14</sup>C-choline into phospholipids of normal or transformed hamster embryo fibroblasts.

We compared the patterns of labelling of glycoproteins of the cell membranes of both normal and ara-C treated cells

<sup>14</sup> C-CMP-sialic acid	740	220	70	

Transformed cells were pre-incubated in Petri dishes until approximately half monolayered as described for Fig. 1. After removal of the medium, cells were rinsed with 0.01 M Tris-HCl (pH 7.6) + 0.15 M NaCl and then incubated in a buffer containing sucrose (0.15 M); Tris-HCl, pH 7.6 (40 mM); KCl (15 mM); MgCl<sub>2</sub> (6.6 mM) and MnCl<sub>2</sub> (6.6 mM). Radioactive nucleotide sugars were present at 1 µCi per 3.0 ml incubation medium. Incubation was for 1 h at 37° C. Cells were processed for radioactivity and protein content as described for Fig. 1.

For this purpose, cells with ara-C (10<sup>-3</sup> M) and without ara-C were incubated for 24 h with 3H-D-glucosamine. Thereafter, cell membranes were isolated and washed prior to analysis by means of polyacrylamide gel electrophoresis. The results of these experiments are shown in Fig. 2. Definite differences are seen as regards the distribution of proteins between the normal and ara-C-treated cells. Also, the labelling of the glycoproteins is generally much lower in the ara-C-treated cells as compared with the control cells. Similar results have been obtained with the glycoproteins from cells treated with hydroxyurea.

Various research workers have shown that labelled sugars can be transferred from their activated nucleotide carriers to receptors on the cell surface<sup>8-18</sup>. It is assumed that cell surface glycosyl transferases carry out these reactions. It was of considerable interest to ascertain whether ara-C and hydroxyurea were capable of interfering with these transferase reactions at the cell surface or not. The transfer of labelled D-galactose, D-glucose, N-acetyl Dglucosamine and sialic acid from their respective nucleotide carriers to cell surface glycoproteins was carried out as described in Table 2. It can be seen that ara-C and hydroxyurea inhibit the transfer of galactose, N-acetyl D-glucosamine and sialic acid to a considerable extent, whereas the transfer of glucose does not seem to be affected.

The inhibitions observed could possibly be due to direct interaction of the inhibitors with the glycosyl transferase enzymes of the cell surface (see Table 2). Preliminary experiments with isolated microsomes from transformed hamster embryo cells and rat liver have shown that ara-C (10<sup>-3</sup> M) has no effect on the transfer of labelled sugars from their respective nucleotide carriers to endogenous receptors present in the microsomes. On the other hand, ara-CTP (10-3 M) strongly inhibits the transfer of sugars from their carriers to microsomes. The transfer of UDP-galactose was inhibited by approximately 80%, UDP-N-acetyl-glucosamine and GDP-mannose both by 60% and CMP-sialic acid by 25%. Hydroxyurea (10<sup>-2</sup> M) also inhibited direct transfer of the sugars but to a lesser extent. These preliminary results suggest a direct interference with the glycosyl transferases by the inhibitors discussed. They also suggest that the inhibition of glycoprotein/glycolipid synthesis observed is not due to indirect effects operating through the inhibition of DNA replication.

In the case of ara-C, where presumably the effective inhibitor is ara-CTP, inhibition occurs through direct interaction with the enzyme activating N-acetylneuraminic acid (NANA). Work in our laboratory (L. Parkin and A.O.H., unpublished) with chemically synthesised ara-CTP has shown that the nucleotide inhibits activation in rat liver nuclear extracts11 and with the partially purified enzyme from hog submaxillary glands12. Maximum inhibition has been of the order of 50-60%. We have also shown pre-

viously that ara-CMP (10<sup>-3</sup>-10<sup>-5</sup> M) inhibits the transfer of NANA from CMP-NANA to receptors by approximately 20%. It seems therefore that ara-C as its triphosphate is inhibiting both the activation and subsequent transfer of NANA to receptors. The effect of ara-CTP on the transfer of other activated sugars to receptors in isolated microsomes is of considerable interest. These are direct effects and are under study at the moment.

## Assignment of the human gene for galactokinase to chromosome 17

EVIDENCE presented here and in the report by Elsevier et al.1 mutually establishes the assignment of the human gene for galactokinase (EC 2.7.1.6), the enzyme which converts galactose to galactose-1-phosphate, to chromosome 17. This assignment is based on a syntenic relationship between the genes for thymidine kinase and galactokinase.

Hybridisation of rodent and human somatic cells and the preferential loss of human chromosomes which segregate in the resultant hybrid clones has become an important procedure for assigning human genes to specific chromosomes2. When the HAT selection system3 is used to select hybrids produced by fusion of a thymidine kinase-deficient rodent cell line and a thymidine kinase-positive human cell line, the human gene for thymidine kinase is retained since activity of this enzyme is required for cell survival in HAT medium4. Using this selection system the gene for human thymidine kinase was first assigned to a group E chromosome<sup>5,6</sup>; later specifically to chromosome 17 (ref. 7), and more recently to the long arm of this chromosome8. When HAT selected hybrids are placed in medium containing 5-bromodeoxyuridine (BrdU), the incorporation of this thymidine analogue into DNA, made possible by thymidine kinase activity, is lethal, thereby producing selection against cells retaining the thymidine kinase gene9. Furthermore, the hybrid cells which can grow in medium containing BrdU, have lost the human chromosome 17 (ref. 9).

The hybrid clones analysed for human galactokinase activity were derived independently from five separate fusion experiments involving mouse (CI1D) and human (KOP-2, LNSV and W18Va2) parental cell lines. These parental cell lines and the procedures used for cell fusion have been described before. After fusion, hybrid cells were maintained in HAT selective medium and subsequently cloned. Each clone was derived from a different hybrid cell colony. Nine of the HAT selected hybrid cell clones were transferred to medium containing 30 µg ml<sup>-1</sup> BrdU and maintained in it for at least 30 passages. Mouse and human chromosomes were identified in each of the hybrid cell clones by Giemsa-banding as previously described. A minimum of 20 metaphases from each hybrid cell clone was analysed to identify the human chromosomes present.

Thirty-two human-mouse hybrid cell clones were tested for the presence of human galactokinase. Extracts of these hybrid clones were electrophoresed in starch by the methods of Tedesco et al.<sup>10</sup>. In this procedure, enzyme activity is localised by staining the gel with a reaction mixture<sup>10,11</sup> containing 0.5% Ionagar No. 2 (Consolidated Laboratories Inc.) 0.2 M Tris-HCl, pH 8.0, 7 mM β-mercaptoethanol, 2 mM MgCl<sub>2</sub>, 0.94 mM NADP, 0.6 mM UDP-glucose, 0.21 mM glucose-1, 6-diphosphate, 0.4 mM galactose, 6.6 mM ATP, 0.1 U ml<sup>-1</sup> yeast galactose-1-P uridyl-transferase (Sigma), 0.2 mg phosphoglucom<sup>1</sup>1tase (Boehringer-Mannheim), 0.2 mg glucose-6-phosphate-dehydrogenase (Boehringer-Mannheim), and 0.2 mg

6-phosphogluconate-dehydrogenase (Boehringer-Mannheim). As a final step in the reaction series, NADPH is produced which can be visualised under long wave ultraviolet light. This electrophoretic system easily separates human galactokinase from mouse enzyme, as Fig. 1 shows.

All 23 hybrid clones selected in HAT medium contained the human chromosome 17 and displayed human galactokinase activity (Table 1). On the contrary, nine clones which were back-selected in medium containing BrdU and which have lost human chromosome 17, did not contain human galactokinase activity (Fig. 1 and Table 1).

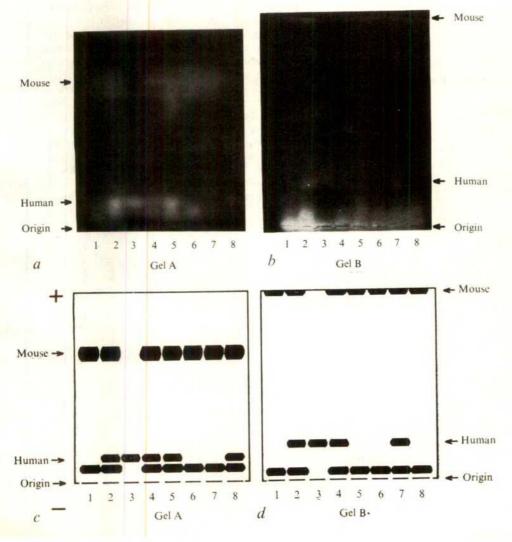

Fig. 1 Two different starch gels stained for galactokinase activity as before<sup>10</sup>, photographed under photographed under long wave ultraviolet light (a and b), c and d are diagrammatic representations of a and b respectively. Galactokinase extracted from mouse (Cl1D) and human (LNSV) parental cells each migrate as a single band of enzyme activity and are well separated in this electrophoretic system. Gel A was run at 8 V cm<sup>-1</sup> and gel B at 10 V cm-1 for 18 h at 4° C. demonstrates the wide degree of separation between human and mouse enzyme obtained in this system. All the hybrid clones tested were run with the higher voltage to obtain more effective of human galacseparation tokinase from the nonspecific staining that occurs near the origin in these gels when galactose deleted from the reaction mixture. Under these conditions mouse galactokinase migrates into the anode wick area of the gel. Gel A: channel 1, 52-58 clone 8 BrdU; 2, 52-58 clone 8; 3, LNSV (human parental cell line); 4, 52-58 clone 9; 5, 52-67 clone 21; 6, 52-67 clone 21 BrdU CIID (mouse parental cell line) 8, 52-58 clone 19. Gel B; channel 52-58 clone 8 BrdU; 52-58 clone 8; 3, LNSV; 4, 52-58 clone 9; 5, 52-58 clone 3 BrdU; 6, Cl1D; 7, 52-67 3 BrdU; 6, Cl1D; 7, 52-67 clone 21; 8, 52-67 clone 21 BrdU In gel A channels 1 and 2 and 5 and 6, and in gel B channels 1 and 2 and 7 and 8 represent pairs of HAT selected clones before and after BrdU selection.

These data demonstrate the syntenic relationship between human galactokinase and thymidine kinase and allow the assignment of the human gene for galactokinase to chromosome 17.

## **Opossum Hb chain sequence** and neutral mutation theory

THE divergence of amino acid sequences which has accompanied evolution of species may be largely due to random fixation of selectively neutral or nearly neutral mutations. This was proposed by Kimura upon consideration of an inferred rapid rate of molecular evolution, the theory of the cost of natural selection, and observed high levels of polymorphism in natural populations. Among the observations considered to favour the neutral mutation-random fixation theory<sup>1-4</sup>, the apparent uniformity of the rate of fixation of amino acid substitutions in homologous proteins along several phyletic lines is outstanding. Kimura proposed this test of the neutral mutation theory by examining the amino acid sequences of proteins from so-called 'living fossils<sup>14</sup>. If, for a very long slowly evolving line, a rate of molecular evolution equal to that of more rapidly evolving lines is inferred (and it is assumed that the rate of evolution of physiological adaptations generally parallels the morphological evolutionary rate) then a case is made for the fixation of neutral mutations. The amino acid sequence proposed here<sup>5</sup> (Fig. 1) for the α chain of haemoglobin from a 'living fossil'6, Didelphis marsupialis, the Virginia opossum may be taken for such a test of the neutral mutation theory.

Since only a single haemoglobin component was found by gel electrophoresis7, chain separation8 was done on globin prepared from fresh haemolysate. Cyanogen bromide treatment's of the a chain yielded fragments containing residues 1-25, 26-76, 110-125, and 126-141; treatment with citraconic anhydride10, ethyleneimine11, and trypsin gave fragVal-Leu-Ser-Ala-Ash-Asp-Lys-Thr-Ash-Val-Lys-Gly-Ala-Try-Ser-Lys-Val-Gly-Gly-Asn-Ser-Gly-Ala-Tyr-Met-Gly-Glu-Ala-Leu-Tyr-Arg-Thr-Phe-Leu-Ser-Phe-Pro-Thr-Thr-Lys-Thr-Tyr-Phe-Pro-Asn-Tyr-Asp-Phe-Ser-Ala-Gly-Ser-Ala-Gln-Ile-Lys-Thr-Gln-Gly-Gln-Lys-Ile-Ala-Asp-Ala-Val-Gly-Leu-Ala-Val-Ala-His-Leu-Asp-Asp-Met-Pro-Thr-Ala-Leu-Ser-Ser-Leu-Ser-Asp-Leu-His-Ala-His-Glu-Leu-Lys-Val-Asp-Pro-Val-Asn-Phe-Lys-Phe-Leu-Cys-His-Asn-Val-Leu-Val-Thr-Met-Ala-Ala-His-Leu-Gly-Lys-Asp-Phe-Thr-Pro-Glu-Ile-His-Ala-Ser-Met-Asp-Lys-Phe-Leu-Ala-Ser-Val-Ser-Thr-Val-141 Leu-Thr-Ser-Lys-Tyr-Arg

Fig. 1 Proposed amino acid sequence for Didelphis marsupialis haemoglobin a chain.

ments containing residues 1-31, 32-102, and 103-141. Fragments were identified by compositions and sequences of tryptic peptides derived from them: identification of each tryptic peptide was generally inferred from obvious homology with a chains of known sequence. Identification of the peptide containing residues 57-61 was made by compositions of the parent fragments and identities of the other tryptic peptides derived from those fragments. Fragments and peptides were purified with columns of Sephadex or cation-exchange resins12. Sequence determination of the tryptic peptides was done by further enzymic or chemical cleavage and the subtractive Edman technique13. Amides were determined by aminopeptidase M digestion14 or glycinamidation15. (Full details of the structure determination will be published elsewhere.)

In Fig. 2 the number of sequence differences between members of several pairs of vertebrate  $\alpha$  chains<sup>18-24</sup> are listed. The opossum  $\alpha$  chain has apparently evolved more rapidly than any other a chain in all cases in which a comparison is possible. This result exceeds the expectations of the neutral mutation theory. A selectionist interpretation of the more rapid rate of molecular evolution in a living fossil is possible: if the evolutionary rate is limited by the cost of natural selection28-27 then one may expect to find an

### Preservation of antigenic properties of macromolecules over 70 Myr

It has been known for some time that many fossils still contain remnants of organic macromolecules, such as proteins and polysaccharides1. Such macromolecules are often enclosed inside the mineralised tissues of fossils, well protected from outside influences. This close association of skeletal, mineral and macromolecular substances, which is also found in recent mineralised tissues, suggests that this organic material has been an important factor in the process of mineralisation and has deeply influenced the physical properties of the skeletons<sup>2,3</sup>. It cannot be excluded however, that organic substances not involved in mineralisation can also be preserved in sedimentary rocks without much loss of their original structure, provided that they are well enclosed in the sediment. With this reserva-

tion in mind, characterisation of the structure of enclosed substances may yield valuable palaeobiochemical and diagenetical information.

Fossil macromolecules are often very complex, may occur in a great variety and may contain multiple decomposition products. Chemical analyses have hitherto been confined mainly to qualitative and quantitative determinations, such as amino acid analyses. In this paper we show that immunological techniques are very useful for the comparison of fossil and recent material from different sources. They may also be of value for the study of diagenetical processes.

We investigated cephalopods because fossil as well as recent representatives are readily available and contamination can easily be eliminated. Shells of the recent Sepia officinalis from the Dutch coast, of Nautilus pompilius (recent-Indian Ocean) and of Belemnitella junior (Maastrichtian-Maastricht, Netherlands) were scrupulously cleaned from organic and inorganic contamination and ground to a fine powder. Each powder was then decalcified in excess of 10% EDTA solution (pH 8) and insoluble residues were removed by centrifugation (30 min at 20,000g). The supernatant was concentrated and dialysed with an Amicon PM 10 filter until free of EDTA. One ml aliquots containing 1-2 mg material from Sepia and Belemnitella were injected with complete Freunds adjuvant into rabbits three times subcutaneously at intervals of two weeks. Against each antigen two antisera were prepared (AS, and ASI) against Sepia and AB1 and AB11 against Belemnitella). Extracts from the three different sources were compared in the Ouchterlony technique (Fig. 1). When the three extracts were allowed to react with preimmunisation sera, no precipitates were found. All the precipitates described are therefore immunoprecipitates.

Both Sepia antisera reacted with Sepia, Belemnitella and Nautilus extracts (Figs 1a and b). Depending on the antigen preparation (S<sub>1</sub> or S<sub>2</sub>) used, one or two precipitation lines were formed (Figs 1a and b). The AS11 serum indicates crossreactivity between Sepia and Belemnitella antigens, which is not shown with the AS<sub>1</sub> serum (Figs 1a and c). The AS<sub>11</sub> serum also detects crossreactivity between the Nautilus and Belemnitella antigens (Fig. 1d). Both AS sera produce very sharp lines with the Nautilus extract (Figs 1b and e). When tested with the AS<sub>1</sub> serum, no crossreactivity between the Sepia and Nautilus antigens is seen (Fig. 1e). This may be due to either the absence of the crossreacting antigen from the  $S_1$  antigen preparation (Figs 1a and b) or a crossreactivity between the Nautilus antigen and a hidden determinant of the Sepia antigens.

The experiments with the anti-Belemnitella sera produced only weakly visible patterns. From Fig. 1f it is clear, however, that single precipitation lines are formed with Belemnitella and Nautilus extracts indicating complete crossreactivity. The Sepia extract does not react with anti-Belemnitella serum, although the Belemnitella extract does react with the anti-Sepia sera (Figs 1a and c). This may indicate a weaker immunogenicity of the Belemnitella extract. From these experiments the following conclusions can be drawn. First, fossil as well as recent calcified tissues have been found to contain organic material with antigenic properties; second. because certain fractions from Belemnitella still crossreact with extracts of shells from recent Sepia (partially) identical structures have been retained in the fossil macromolecules for over 70 Myr. Third, the reactions of the Nautilus extract with the anti-Sepia and anti-Belemnitella sera suggest that the skeletal macromolecules in question have undergone minor alterations since the lower Carboniferous, when the Coleoids are thought to have diverged from the Nautiloid lineage. In evolutionary terms these must have been extremely conservative substances.

The antigenic relationship of the skeletal macromolecules of Cephalopods and related taxa is now being worked out in detail in our laboratory. The possibility of antigen localisation in sedimentary rocks by immunological techniques at light-

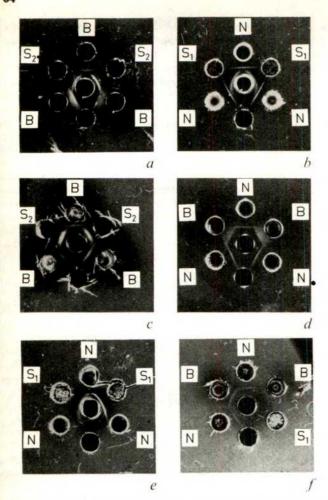

Fig. 1 Immunodiffusion patterns of extracts from shells of Sepia officinalis, Nautilus pompilius (both recent) and 70-Myrold Belemnitella junior. and electron-microscopical level is also being investigated. Determination with immunological techniques of the phylogenetic relationship of taxa with unknown systematic position, such as the stromatoporoids, is yet another project which we intend to investigate in the near future.

We would like to thank Drs L. Bosch and M. A. Crenshaw for their continuous interest in our work and for critically reading the manuscript. Sepia officinalis and Nautilus pompilius material was provided by the Rijksmuseum voor Natuurlijke Historie, Leiden, and Belemnitella junior material was provided by the Rijksmuseum voor Geologie en Mineralogie, Leiden. Shells were powdered by Mr K. K. H. Knies, Geologisch en Mineralogisch Instituut, Leiden, and sera were prepared by Mr F. Leupe and his staff, Department of Medical Microbiology, State University, Leiden. Part of this investigation was made possible by grant from the Netherlands Organisation for the Advancement of Pure Research (ZWO).

# Defective membrane synthesis in an *E. coli* mutant

THERE is a strict correlation between DNA synthesis and cell division1,2 but there is no known relationship between cell division and membrane synthesis-presumably because so little is known about the latter. We have previously reported that the formation of cytochrome  $b_1$  and the L- $\alpha$ -glycerophosphate uptake system occurs at the same time (in a discontinuous manner) at a particular phase in a cell cycle of Escherichia coli (ref. 3). On the basis of these observations we attempted to isolate a phase-specific mutant which has a defect in the formation of membrane components. The selection of the mutants was carried out assuming that cell growth is temperature-sensitive and that the formation of the β-galactoside transport system is under the control of the corresponding ts-mutation. These assumptions were based on the observation that the formation of the transport system for  $\beta$ -galactoside, measured using a synchronous culture, completely coincided with those of many membrane components including cytochrome b1 (M.O., unpublished) and on the consideration that cells defective for such processes should be non-viable4.

Here we present evidence that the mutant we isolated is unable to form cytochrome  $b_1$ , an  $L-\alpha$ -glycerophosphate transport system, an  $L-\alpha$ -glycerophosphate dehydrogenase and succinate dehydrogenase at a non-permissive temperature, because of a single mutational defect in a phase-specific function which operates 20–30 min before cell division. We also postulate two alternative functions of a protein which is synthesised or activated at 20–30 min before cell division. First, that the protein controls the fabrication of the active forms of membrane components, and, second, that the protein regulates a concurrent expression of the genes responsible for cytochrome  $b_1$  and so on, thus resulting in alignment of a population at a specific phase of cell division at a non-permissive temperature.

The mutant tsC42, described here, grows at a normal rate at 30° C but it stops growing at 42° C. Figure 1 shows that protein synthesis takes place at 42° C. The increase in the amount of protein began rapidly but gradually stopped. Finally, it reached a level of 1.7–1.8 times the original amount. The turbidity of the culture, the amount of protein and viable

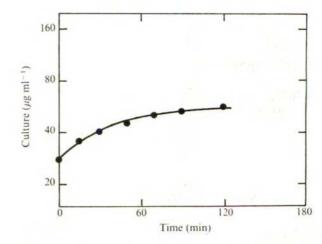

Fig. 1 Synthesis of protein in the mutant tsC42. Cells were grown in A medium<sup>5</sup> for several generations at 30°C and transferred to 42°C. Samples were withdrawn at the times indicated. Protein was measured by the method of Lowry et al.<sup>5</sup>.

Wyckoff, R. W. G., The Biochemistry of Animal Fossils (Scientechnica Ltd, Bristol, 1972).

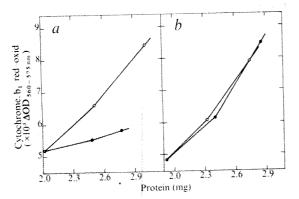

Fig. 2 Formation of cytochrome  $b_1$  in the mutant tsC42 and the parental strain AT713. Cells were grown in A medium<sup>5</sup> for more than three generations at 30° C and the culture divided into two parts. One portion was heated to 42° C and the other was further grown at the same temperature. Samples were removed after 20 and 40 min in the incubation at 42° C ( $\blacksquare$ ) and 30 and 60 min in the incubation at 30° C ( $\blacksquare$ ). The amount of cytochrome  $b_1$  was determined as described previously<sup>3</sup>. a, tsC42; b, AT713.

cells remained constant for a long period of incubation after initial increases. The size of the cells accumulated during incubation at a non-permissive temperature were homogeneous and almost equivalent to the larger cells of a cell population growing randomly.

Cytochrome  $b_1$  is the major component of cytochromes in  $E.\ coli$  and a membrane-bound constituent which is constitutively synthesised<sup>3</sup>. Figure 2 shows the results of experiments in which the formation of cytochrome  $b_1$  was measured in the mutant tsC42 and the parent AT713. The rate of formation was greatly reduced at  $42^{\circ}$  C, compared with  $30^{\circ}$  C in the mutant tsC42 (Fig. 2a), while their rates were essentially identical in the parent AT713 (Fig. 2b).

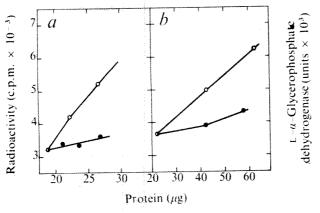

Fig. 3 Formation of L-α-glycerophosphate transport and L-α-glycerophosphate dehydrogenase in the mutant tsC42. Cells were grown in A medium<sup>5</sup> supplemented with 0.04 M DL-α-glycerophosphate. The assay of <sup>14</sup>C-L-α-glycerophosphate uptake in samples withdrawn after 30 and 60 min incubation at 30° C (○), and 20, 40 and 60 min at 42° C (♠), was carried out according to the method of Hayashi et al.<sup>7</sup>. For the assay of L-α-glycerophosphate dehydrogenase, samples were withdrawn after 30 and 60 min incubation at 30° C (○) and 20 and 40 min incubation at 42° C (♠) and the cells were washed twice with 0.1 M phosphate (pH 7.4) at 0° C and suspended in the same buffer. The cells were disrupted by treatment in a Umeda 20 kc 150 W sonic oscillator for 1 min and the unbroken cells were removed by centrifugation at a low speed. The enzymatic activity was assayed by measuring the rate of reduction of DCIP (2,6-dichlorophenol-indophenol) essentially according to the procedure of Lin et al.<sup>8</sup> except for the use of DCIP instead of MTT and measuring at 600 nm. The assay mixture contained: 0.30 ml cell-free extract, 2.0 ml 0.1 M phosphate at pH 7.4, 0.06 ml DCIP (1 mg ml<sup>-1</sup>), 0.30 ml phenazine methosulphate (1 mg ml<sup>-1</sup>), 0.20 ml 0.15 M KCN and 0.25 ml 0.4 M DL-α-glycerophosphate. One unit corresponds to 1 μmol DCIP reduced min<sup>-1</sup>. a, Transport of <sup>14</sup>C-L-α-glycerophosphate; b, L-α-glycerophosphate dehydrogenase.

Figure 3a shows the inability to form the transport system for L- $\alpha$ -glycerophosphate when the culture of the mutant was transferred into  $42^{\circ}$  C (after a full induction of the system by the supplement of 0.04 M DL- $\alpha$ -glycerophosphate). Since the transport once formed at a permissive temperature was fully active at  $42^{\circ}$  C, and as both the activities at  $30^{\circ}$  C and  $42^{\circ}$  C and the ratio of  $42^{\circ}$ :30° C are almost identical with those of the parental strain AT713, the inability of the inducer transport is not a cause for the absence of formation of the system at a non-permissive temperature. The inability of the mutant to form membrane components is also demonstrated for other enzymes. The results shown in Fig. 3b and 4 are for inducible membrane-bound L- $\alpha$ -glycerophosphate dehydrogenase and succinate dehydrogenase, being a typical and a constitutive membrane enzyme, respectively.

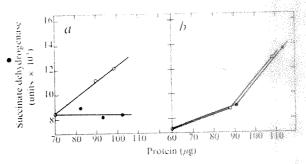

Fig. 4 Formation of succinate dehydrogenase in the mutant tsC42 and the parent AT713. The cultivation of cells and the preparation of the enzyme fraction are the same as described in the legend to Fig. 3 except that the induction by 1-a-glycerophosphate was omitted. The enzymatic activity was measured essentially according to the method described in the legend to Fig. 3. The assay mixture contained: 0.30 ml cell sonicate, 1.60 ml 0.1 M phosphate at pH 7.4, 0.06 ml DCIP (1 mg ml<sup>-1</sup>), 0.30 ml phenazine methosulphate (1 mg ml<sup>-1</sup>), 0.20 ml of 0.15 M KCN and 0.60 ml 0.5 M succinate. A unit corresponds to µmol of DCIP reduced min<sup>-1</sup>, a, tsC42; b, AT713.

The spontaneous reversion frequency to resistant cells at  $42^{\circ}$  C in tsC42 is between  $10^{-6}$  to  $10^{-7}$ ; within that known for single mutations. All three revertants examined were capable of forming cytochrome  $b_1$ , succinate dehydrogenase and L- $\alpha$ -glycerophosphate dehydrogenase at equal rates (increase of activity/increase of protein) at both  $30^{\circ}$  and  $42^{\circ}$  C, indicating that the pleiotrophic defect observed in the formation of several membrane components and cell growth was caused by a single mutation.

Figure 5 shows the patterns of cell division and the formation of succinate dehydrogenase when cells were transferred to 30° C after 35 min incubation at a restrictive temperature (42° C). Cell division occurred synchronously at 35 min and 135 min after a temperature shift to 30° C. The age of cells accumulated during the incubation at 42° C, deduced from the pattern of cell division, corresponds to 0.65 of a generation (designated as zero or one for cells at mid phase of cell division) and is compatible with the observed ages when many membrane components such as cytochrome  $b_1$  were formed during a synchronous growth3. The formation of succinate dehydrogenase occurred immediately after the shift from a non-permissive to a permissive temperature in a discontinuous manner. This result is consistent with the view that because of a defect in the regulation of membrane components formation the whole population of cells aligned at a phase 20-30 min before cell division during an incubation at a non-permissive temperature Furthermore, similar immediate formation was also observed in the case of the L- $\alpha$ -glycerophosphate transport system, thus supporting the above conclusion.

The doubling time (100 min) shown in this figure is comparable with one observed before the exposure to a non-permissive temperature. The synthetic activity of protein was restored promptly as soon as the culture was returned to 30° C. At essentially similar pattern of cell division was also obtained

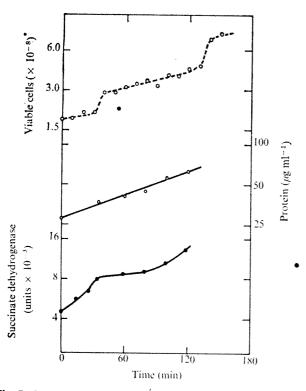

Fig. 5 Cell division and formation of succinate dehydrogenase after incubation at a non-permissive temperature in the mutant tsC42. Exponentially growing cells in A medium were shifted to 42° C and incubated for 35 min. Then the culture was returned to a permissive temperature (30° C) and the increases of viable cells (○---○) grown on a complete agar plate, succinate dehydrogenase (●) and total protein (○—○) were measured. Succinate dehydrogenase was measured according to the method described in the legend to Fig. 4 and units were expressed as µmol of DCIP reduced min<sup>-1</sup> ml<sup>-1</sup>. Total protein was measured according to the method in the legend to Fig. 1.

in the case of 90 min exposure to 42° C. These show that the exposure of cells to a non-permissive temperature had no vital influence and cells remained intact.

Our results indicate that either the conversion from inactive to active forms of the membrane components (or the coordinated expression of the genes responsible for cytochrome  $b_1$  and so on), is under the control of a protein, which is only synthesised or activated 20-30 min before cell division.

Bacterial membranes possess many important biochemical functions such as energy production, active transport, lipid synthesis and cell wall synthesis. They are also special sites for chromosome segregation. To fulfil such complex and ordered roles, membranes are fabricated in a highly organised structural form. The simultaneous formation of many membrane components under the same regulatory mechanism may be an obligatory requirement for the fabrication of membrane units possessing such complex structures from individual precursor molecules. A characteristic feature of the mutant tsC42 is that the mutation is pleiotrophic and the control for cell growth is strict. This means that the functioning or the synthesis of a phase-specific protein is concerned with cell division. Double labelling experiments which discriminate old membrane components from newly-formed ones show that the incorporation of a radioactive amino acid into membrane components was specifically restricted to some membrane components only in non-permissive conditions (M.O., unpublished). Our preliminary experiment presents further evidence for our tentative conclusion that membrane proteins essential for cell growth and cell division are under the strict control of a phase-specific protein with a regulatory function for the formation of membrane components.

Recently Jones and Donachie have reported that cell division is controlled by a protein which is synthesised between termination of chromosome rounds and cell division. Both our and their results show that phase-specific proteins play important roles in cell division.

### Defect in the gamma polypeptide chain of a congenital abnormal fibrinogen (Paris I)

THE primary physiological function of fibringen is fibrin clot formation, a process that requires three distinct reactions. Thrombin first cleaves fibrinopeptides A and B from two of the three pairs of polypeptide chains  $(A\alpha, B\beta, \gamma)$  of fibrinogen<sup>1</sup>, following which the remaining fibrin monomers polymerise spontaneously into an insoluble fibrin clot<sup>2</sup>. Thrombin also converts Factor XIII to an active form, called plasma transglutaminase3, which in turn catalyses the formation of covalent  $\gamma$ -glutamyl- $\varepsilon$ -lysine isopeptide bonds<sup>4</sup> between two  $\gamma$  chains and more than two α chains of different fibrin molecules<sup>5</sup>. The resultant  $\gamma$  chain dimers and  $\alpha$  chain polymers crosslink the fibrin network and render it resistant to chemical or physical modifications.

Any of these three reactions could be impaired by structural defects of fibrinogen, but most of the heritable disorders are associated with either a decreased rate of fibrinopeptide cleavage by thrombin or defective polymerisation of fibrin monomers<sup>6,7</sup>. To date, a specific structural defect has been documented in only one abnormal fibrinogen, Fibrinogen Detroit<sup>8</sup>. The first well-studied abnormal fibrinogen, Fibrinogen Paris I9, showed a strikingly decreased ability to form fibrin polymers after reaction with thrombin and also inhibited the polymerisation rate of normal fibrin monomers. Studies of the fibrin monomers<sup>10</sup> suggested the presence of two populations of fibrinogen molecules in the propositus. Chemical analyses showed that fibrinopeptides A and B6, the NH2-terminal amino acids6, and the Aa chain of the NH2-terminal disulphide knot11 of Fibrinogen Paris I are normal. Here we describe experiments which demonstrate that Fibrinogen Paris I possesses an abnormal y chain, which is probably the cause of the impaired polymerisation of fibrin monomers. In addition, a second functional defect of this molecule will be documented, namely, its inability to crosslink in the presence of Factor XIII.

Fibrinogen (Fraction 1-0) was prepared by the technique of Blombäck and Blömback12 from normal citrated plasma and from citrated plasma of the propositus, in the presence of trypsin inhibitor (Iniprol, Choay, Paris). Factor XIII was obtained from fresh citrated bovine plasma according to the method of Loewy et al13. Human thrombin was supplied by Dr David L. Aronson, Bureau of Biologics, Food and Drug Administration, Rockville, Maryland.

The  $\alpha$  and  $\beta$  chains of non-crosslinked normal and Paris I

fibrin have the same electrophoretic mobility (Fig. 1, gels 1 and 2) and in both cases represent 30% and 36%, respectively, of the total protein, as calculated from densitometric scans (Densicord 552, Photovolt Co., New York). But, the band in the position of normal y chain stains much lighter in Paris I fibrin, and represents only 12% of the total protein compared with 34% in the normal fibrin. In addition, Paris I fibrin has an extra band between the positions of the normal  $\beta$  and  $\gamma$ chains representing 22% of the total protein. From this, Paris I fibrinogen probably contains two molecular populations of  $\gamma$  chain, of which about 35% is normal and about 65% is abnormal. The molecular weight of the abnormal variant of the γ chain is approximately 50,500 ±500, as determined from its migration in SDS-polyacrylamide gel, using standards of normal  $\alpha$ ,  $\beta$  and  $\gamma$  chains, which have molecular weights of 68,000, 56,000 and 48,000, respectively15.

The electrophoretic pattern of reduced normal crosslinked fibrin shows the expected absence of γ and α chains and the presence of  $\gamma$  chain dimers and  $\alpha$  chain polymers (Fig. 1, gel 3). Fibrin formed from Fibrinogen Paris I crosslinks only partially. The normal  $\gamma$  chain is absent and the  $\gamma$  dimer band is present (Fig. 1, gel 4). The abnormal γ<sub>Paris 1</sub> chain persists in the Factor XIII-treated fibrin, apparently not participating in the formation of γ-glutamyl-ε-lysine crosslink bonds. The concentration of a chain in Factor XIII-treated Paris I fibrin is less than in non-crosslinked fibrin. But 66%±15% of the α chains still remain in monomeric form, compatible with the small amount of a chain polymers present in Factor XIII-

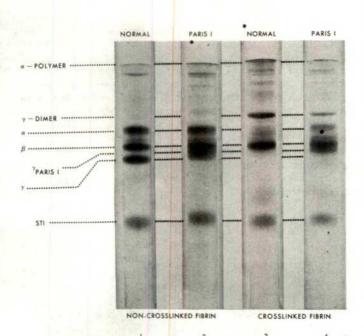

Fig. 1 The electrophoretic patterns in SDS-polyacrylamide gels of reduced fibrin samples obtained from purified normal human fibrinogen and Paris I fibrinogen. Non-crosslinked fibrin was obtained by adding 0.01 ml of human thrombin (100 NIH units ml-1) to a mixture of 0.1 ml fibrinogen (4 mg ml<sup>-1</sup>), 0.01 ml of soybean trypsin inhibitor (10 mg ml<sup>-1</sup>) (Sigma), 0.01 ml of freshly purified bovine Factor XIII (2 mg ml<sup>-1</sup>) and 0.01 ml of 0.1 M EDTA. Crosslinking of fibrin was accomplished by adding thrombin to a similar reaction mixture, except that 0.01 ml of 0.01 M calcium chloride was substituted for the EDTA. Reaction mixtures were incubated at 37° C for 24 h and then at 0° C for 1 h. After incubation, 0.015 ml of ethanol was added and the clots were dissolved by adding 0.5 ml of a solution containing 9 M urea, 3% sodium dodecyl sulphate and 3%  $\beta$ -mercaptoethanol and incubating at 37° C for 2 h. Aliquots of 5 µg of protein were subjected to SDS-polyacrylamide gel electrophoresis, performed according to the method of Weber and Osborn<sup>14</sup>, and gels were stained with Coomassie Brilliant Blue<sup>14,15</sup>. The rapidly migrating band present in the lower portion of each gel is soybean trypsin inhibitor (STI), which was added as an internal electrophoretic standard.

treated Paris I fibrin (Fig. 1, gel 4). The amount of a chain which does not participate in polymer formation correlates well with the proportion of γ chains that are abnormal (γ<sub>Baris 1</sub>). Since the a chains in Paris I fibrin are otherwise normal in appearance, this suggests that the failure of the abnormal YParis I chains to form dimers prevents the a chains of the same molecule from undergoing polymerisation. Thus, of the two varieties of fibrinogen in the plasma of the propositus, only those molecules with normal y chains undergo crosslinking of both the y and the a chains. This is supported by determination of the urea-soluble fibrin present in Factor XIII-treated Paris I fibrin. Overnight extraction with 5 M urea dissolves approximately 60% of the total fibrin, correlating well with the proportion of  $\gamma$  and  $\alpha$  chains in Paris I fibrin that does not crosslink. These changes are not the result of a Factor XIII defect, since this activity was normal in both the propositus and his father6.

The abnormal γ<sub>Paris I</sub> chains are about 2,500 daltons heavier than the normal y chains, corresponding to an additional polypeptide chain of about 22 amino acid residues. Since it is known that crosslinking of  $\gamma$  chains involves the glutamine and lysine residues in positions 14 and 6, respectively, from the carboxy-terminal end16, and since the NH2-terminal amino acids of Fibrinogen Paris I are the same as those of normal fibrinogen6, the molecular defect appears to involve the COOHterminal region. The heavier molecular weight of the Yparls I chain suggests that the structure is so altered as to impair the proper alignment of fibrin monomers for both polymerisation and Factor XIII-induced stabilisation. As such, this is the first documented example of an abnormal fibrinogen which

fails to crosslink. We thank Miss Margery E. Parker and Mrs Penny Shames for technical help. This work was supported by grants from the National Heart and Lung Institute. V.J.M. is the recipient of a Research Career Development Award from the National Heart and Lung Institute.

### Carcinogenic polynuclear hydrocarbons bind to macromolecules in cultured human bronchi

THE ability of cells in human tissues to metabolise procarcinogens into oncogenic metabolites may be one important determinant in organ and host susceptibility to environmental carcinogens. Metabolic activation of polynuclear aromatic hydrocarbons (PNH) seems to be required before they can cause neoplastic transformation of cells either in vivo or in vitro1.2. This activation may involve the production of a metabolite(s) capable of tight binding to cellular macromolecules including DNA. The binding level of PNH to macromolecules generally shows a good correlation with their oncogenicity in experimental animals and cells in culture3-6, although exceptions exist7. Whether or not this correlation exists in man is unknown.

We report here that human bronchial epithelial cells in organ culture have the capability to bind and presumably to activate PNH [7.12-dimethyl benz(a)anthracene (DMBA): 3-methylcholanthrene (MCA); benzo(a)pyrene (BP) and dibenz(a,h)anthracene (DBA)]. Binding to DNA was measured by biochemical methods while total binding to epithelial cell macromolecules was shown by autoradiography. These methodologies had been previously developed in studies utilising an animal model of human lung

Bronchi were obtained as surgical specimens from three patients with lung cancer and from one patient without lung cancer. Grossly normal-appearing pieces of bronchi were immediately immersed in L15 medium10 at 4°C until cultured. The bronchi were then cut into approximately 1×1 cm squares and placed in 60 mm plastic Petri dishes with the epithelium oriented toward the gas-liquid interface. Two ml of CMRL 1066 medium<sup>11</sup> containing 1 µg ml<sup>-1</sup> crystalline insulin, 0.1 µg ml<sup>-1</sup> hydrocortisone hemisuccinate, 0.1 μg ml<sup>-1</sup> β-retinyl acetate, 100 units ml<sup>-1</sup> penicillin G, 2 mM L-glutamine and 100 µg ml<sup>-1</sup> streptomycin were added to each dish17. Cultures were maintained in an air-tight box and gassed with 50% O2, 45% N2 and 5% CO2 for 5 min. The medium was replaced and the cultures were gassed every 2 d. The box containing the cultures was rocked in the dark at approximately 10 cycles min-1 so that the bronchial tissue was submerged half of the time. Cultures were incubated at 36.5° C.

At 7 d, tritium labelled PNH (3H-DMBA, 14.5 Ci mmol-1, (Amersham/Searle,); <sup>3</sup>H-MCA, <sup>5</sup> Ci mmol<sup>-1</sup> (Amersham/Searle); <sup>3</sup>H-BP, <sup>17</sup> Ci mmol<sup>-1</sup>, (Amersham/Searle) and <sup>3</sup>H-DBA, <sup>2</sup>42 Ci mmol<sup>-1</sup> (New England Nuclear)) were dissolved in dimethyl sulphoxide (final concentration 0.5%) and added to the culture medium at a final concentration of 40 µCi ml<sup>-1</sup>. The radiopurity of these compounds was determined by radioscan of thin layer chromatograms. When necessary the compounds were repurified by chromatography8 to a radiopurity of greater that 99%. Following incubation for 24 h, the bronchial tissues were washed three times with cold Dulbecco's phosphate-buffered saline. For autoradiography four cultures per experimental variable were fixed overnight in 3% glutaraldehyde buffered by 0.1 M s-collidine, pH 7.4, and then postfixed in 1.33% OsO4 in the same buffer. As

Table 1 Specific activities of binding of tritium-labelled polynuclear hydrocarbons to human bronchial DNA

Polynuclear	Specific activity*						
hydrocarbon	(d.p.m. per µg DNA)	(pmol per mg DNA)					
DMBA	170 ± 22† (3)‡	53+7					
BP	224 + 77 (4)	$40 \pm 14$					
MCA	$38\pm 9$ (2)	34+8					
DBA	$15\pm 3$ (3)	28±6					

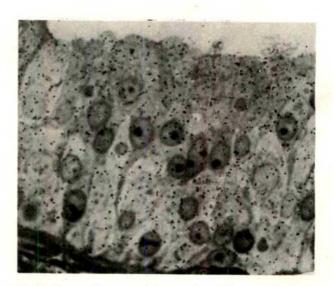

\* The amount of DNA and d.p.m. were determined from the peak DNA fraction of CsCl gradients. See text for specific activities (Ci mmol<sup>-1</sup>) of tritiated PNH.

†Mean ± s. e. ‡Number of cases studied.

previously described, tissues were repeatedly washed in dehydrating solutions of ethanol to remove unbound PNH; The radioactivity released into the dehydrating solutions was monitored by liquid scintillation methods. The tissues were then embedded in Epon 812 containing 5% Araldite 502, 1 μm sections were cut, and autoradiograms were prepared12

Radioactivity was found in both the nuclei and cytoplasm of epithelial cells incubated with 3H-DMBA (Fig. 1). Ciliated, mucous and basal cells contained tightly bound radioactivity. Epithelial cells in bronchial glands were overlaid also with autoradiographic grains. Similar results were found with 3H-BP, 3H-MCA and 3H-DBA. Quantitative analysis of the autoradiograms will be reported fully elsewhere. Bound radioactivity was also found in mesenchymal cells, but to a lesser extent. This observation is consistent with the finding that human embryonic lung fibroblasts are capable of activation and binding of PNH in vitro13. For biochemical studies, bronchial mucosa cells were scraped from the supporting cartilage. Cells from six cultures were pooled for each carcinogen-case combination. DNA was isolated from these cells, and the results of CsCl gradients of the purified DNA are shown in Fig. 2 and Table 1. In the cases studied to date, DMBA and BP bind to DNA more than DBA.

We wished to determine if a major target tissue of environmental carcinogens, the human bronchus, had the capability to activate PNH into forms which tightly bind to macromolecules. It is apparent that the human bronchial mucosa has this capability after it has been maintained

Autoradiogram of human bronchial epithelial cells following in vitro incubation with 3H-DMBA (40 μCi ml-1) for 24 h. Autoradiographic grains are found overlying both nuclear and cytoplasmic sites. One micrometre section stained with toluidine blue (×880).

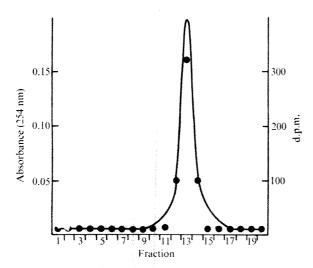

Fig. 2 CsCl gradient profile of DNA purified from human bronchial mucosa. After 7 d in organ culture, bronchial pieces were incubated with  ${}^{3}\text{H-MCA}$  (40  $\mu\text{Ci ml}^{-1}$ ) for 24 h. The bronchial mucosa containing epithelial and mesenchymal cells was then scraped from supporting structures and a crude preparation of DNA was obtained by phenol extraction and precipitation with 50% ethanol. The precipitate was repeatedly extracted with ether and benzene to remove unbound tritiated PNH and sequentially digested with RNase (Worthington Biochemicals) and Pronase (Calbiochem). The aqueous solution of DNA was extensively (Worthington Biochemicals) and Pronase dialysed and then banded on CsCl gradients (Beckman SW56 rotor, 35,000 r.p.m.; 66 h, 25° C). Gradients were fractionated into 0.2 ml portions, and absorbance and radioactivity were determined on each fraction. The absorbance (—) was continuously monitored at 254 nm; radioactivity (d.p.m.) is indicated by the points. Each gradient contained approximately 10 µg of DNA.

in organ culture for 7 d. This finding is consistent with previous studies<sup>14,15</sup> showing morphological changes in human respiratory epithelium caused by PNH in vitro.

As this system becomes better defined, it may be used to determine the individual variations of binding activity in groups at different risks to bronchogenic carcinoma; in adition this system may be useful in evaluating experimental attempts to modify and inhibit the activation of PNH in the human bronchial epithelium. Studies comparing the level of PNH binding to DNA in a large number of individuals with and without lung cancer are needed. If groups at high risk to develop lung cancer can be identified then steps to intervene can be taken<sup>16</sup>. We thank William Kaufmann, Frank Jackson and Maria Yamaguchi for technical assistance. The comments of Drs Yuspa, Sporn, Saffiotti and Janss were appreciated by the authors. This work was supported in part by a National Cancer Institute contract.

### Dose-related inhibition of chemical carcinogenesis in mouse skin by caffeine

THERE is some evidence that caffeine protects against the effects of chemical carcinogens<sup>1,2</sup>. Leitner and Shear<sup>3</sup> found a reduction in the effectiveness of benzo(a)pyrene as a carcinogen when it was administered by subcutaneous injection together with various purines, including caffeine. An enhancement of the antitumour effect of 1,3-bis(2-chloroethyl)-1nitrosourea by caffeine has been reported4 but whether the caffeine acts as an anticarcinogen or as a membrane-active agent (a property of caffeine which has been demonstrateds) is not clear. Tumour production in vivo has been shown to be partially suppressed by theophylline<sup>6</sup> and it is possible that caffeine which is chemically closely related to theophylline may similarly suppress tumour production.

We have shown that caffeine inhibits the carcinogenic action of cigarette smoke condensate fractions when added to the fractions before application. Our experiments were prompted by unexpected results obtained when testing fractions of cigarette smoke condensate for carcinogenicity. Traces of caffeine, remaining after a fractionation procedure involving caffeine7, were found in fractions which showed reduced carcinogenicity when applied to mouse skin. The effect of caffeine was then tested systematically.

Two fractions of smoke condensate, from plain cigarettes manufactured from flue-cured tobacco representing the major plain cigarette brands smoked in the United Kingdom, were prepared by standard methods7-9 and applied repeatedly to mouse skin at two dosages either alone or together with caffeine, also at two concentrations. Dose levels of condensate fractions refer to the amount of smoke condensate from which the fraction was derived; thus an application of 150 mg of a fraction which represented 25% by weight of the parent condensate is referred to as a 600 mg dose. All treatments were given as solutions/suspensions in 0.3 ml of isopropanol: acetone (20:80) three times weekly until the last mouse died (112 weeks). Procedures used for animal husbandry, skin shaving, the application of fractions, post mortem and histopathological examination of mouse skin were as previously described9,10

The two fractions tested were: first, fraction G, a cyclohexane soluble fraction, prepared from smoke condensate by removal of water soluble materials followed by distribution of the water insoluble phase between 90% methanol and cyclohexane<sup>8</sup>. This fraction, representing 25% by weight of the original condensate, accounted for 80% of the carcinogenic activity of the condensate. Second, fraction RP prepared by extracting a cyclohexane solution of fraction G with a 15% w/v solution of caffeine in 90% formic acid followed by removal of the caffeine?. This fraction, representing 3.3% by weight of

the original smoke condensate, accounted for more or less all the carcinogenic activity of the parent fraction, G. The concentration of caffeine added to the mouse painting solutions were: 0.04% of the smoke condensate equivalent (that is,  $0.24~\mathrm{mg~week^{-1}}$  for a 600 mg dose and  $0.12~\mathrm{mg~week^{-1}}$  for a 300 mg dose) or 0.2% of the smoke condensate equivalent (that is 1.2 mg week<sup>-1</sup> for a 600 mg dose and 0.6 mg week<sup>-1</sup> for a 300 mg dose). Caffeine was also tested alone at doses of 0.24 mg week -1 and 1.2 mg week -1.

The results, given in Table 1, are presented as percentage of animals bearing one or more benign or malignant tumours (TBA), percentage of animals bearing carcinomas showing invasion of the panniculus muscle on microscopic examination (CBA) and the relative incidence rates for tumours and carcinomas.

The relative incidence rate parameter, b, is obtained by the fit of a Weibull distribution which postulates that the incidence rate at time t, in treatment group i, is given by the expression  $b_i k(t-w)^{k-1}$  in which k and w are independent of the treatment<sup>11</sup>. The relative incidence rate is a better measure of effect than are simple percentages as it compensates for different mortality rates in the groups.

From the results it is clear that caffeine alone did not lead to the development of skin tumours. To evaluate the effect of the three variables (fraction, dose and caffeine) in the other groups, the method of Weibull multiple regression was used12. The analysis showed that there was a highly significantly greater response (P<0.001 for both TBA and CBA) at 600 mg dose levels than at 300 mg dose levels. In fact the response at 600 mg was, on average, 2.2 times greater than at 300 mg for tumours and was 2.6 times greater for carcinomas. At the higher caffeine concentration, the caffeine significantly reduced tumour incidence (P<0.001 for TBA and <0.005 for CBA). At the lower caffeine concentration, there was also a reduction in tumour incidence but the effect was not statistically significant. There was no evidence of a difference in response between the two fractions, nor of any interaction between the three factors: fraction, dose of fraction and concentration of caffeine.

Although it is not known how caffeine brings about these effects, it is known that purines form complexes with polycyclic aromatic hydrocarbons (PArH) and heteropolycyclic compounds. Both these chemical classes have representative compounds in cigarette smoke condensate and some members of both classes are chemical carcinogens. The complexing is relatively weak in the case of the PArH; resulting from a dipole-induced dipole interaction between the polar component (caffeine) and the polarisable component (the aromatic compound).

Attempts have been made to relate complexing ability of PArH to their carcinogenic properties, but none has been successful1,2. It is nevertheless possible that the complexing property of PArH makes an important contribution to their carcinogenicity, the differences in their activity resulting from a combination of factors such as molecular size, geometry and general reactivity. Thus, the absence of carcinogenic activity in the majority of PArH might arise from diffusion and transport difficulties within the cell or a lack of ability to adapt to a favourable configuration at the site of action within the cell. The inhibition of carcinogenesis by caffeine could result from competition for the polycyclic compound between the site of action in the cell and the caffeine.

The possibility that caffeine may inhibit transport of PArH through cell membranes cannot be overlooked, but caffeine can facilitate the transport of some compounds through membranes, so this explanation seems unlikely.

Both caffeine and theophylline are known to affect the level of adenosine 3', 5'-cyclic monophosphate (cyclic AMP) in mammalian cells13. It has been suggested that a partial suppression of tumour production by theophylline was due to an effect on cyclic AMP synthesis6 and caffeine may inhibit tumour production by a similar mechanism. If this were the correct explanation, caffeine could be expected to act as an inhibitor of chemical carcinogenesis in general and not specifically of polycyclic hydrocarbon induced carcinogenesis. This possibility can therefore be tested.

### Caffeine inhibits induction of endogenous C-type virus

Endogenous C-type viruses can be induced by treating the rodent cells in which they reside with halogenated pyrimiding analogues, notably 5-iodo-2'-deoxyuridine (IUdR) (refs 1, 2). Here I show that caffeine, which inhibits repair of photolesions and interacts with DNA in various ways<sup>3</sup>, inhibits the induction of the endogenous virus by IUdR.

The MLg cell line originating from a newborn ddY mouse was used; this cell line was found to release C-type virus after IUdR treatment'. The induced virus was detected by the XC test5.

The frequency of virus production was estimated as follows. MLg cells inoculated in 60 mm plastic Petri dishes (10<sup>s</sup> cells per dish) were treated with IUdR (5-50 µg ml<sup>-1</sup>) for 24 h; the medium was removed and untreated MLg cells (103 cells per dish) were laid over the IUdR-treated cells. Three days later, three subcultures were made; after a further 3 d, the cultures were submitted to the XC plaque titration test. For IUdR concentrations of 5, 20 and 50 μg ml<sup>-1</sup> the mean plaque number per dish was 19, 73 and 125, respectively, A proportional relation between plaque number and IUdR concentration was observed. There was some variation of induction frequency from one experiment to another, but the variation was small within one experiment, (see Fig. 1a). In the subsequent experiments, the concentration of IUdR was used at 25 µg ml<sup>-1</sup> for 24 h.

The cells were treated with caffeine (0.625 to 5 mM) for 24 h before or after IUdR treatment (25, µg ml<sup>-1</sup> for 24 h). Twenty-four hours after the removal of IUdR, the cultures were overlaid with normal MLg cells (10<sup>5</sup> cells per dish). Three days later, each culture was divided into three, and

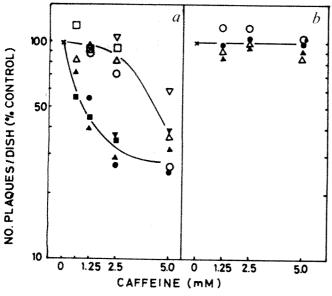

Fig. 1 a, Effect of caffeine on endogenous C-type virus induction. Closed symbols indicate caffeine treatment after IUdR (2 ml-1), and open symbols indicate caffeine treatment before IUdR. Four repeated experiments are shown. The mean number of plaques per dish was obtained from three cultures which were derived from one plate. In some experiments, 2 cultures were prepared for the control; the mean plaque number in this case is the mean of the two values obtained. The mean plaque number of the control was 129 for experiment  $1(\bigcirc, \bigoplus)$ , 134 and 119 for experiment  $2(\triangle, \triangle)$ , 114 and 98 for experiment 3 ( $\square$ ,  $\blacksquare$ ), and 95 and 85 for experiment  $4(\nabla, \blacktriangledown)$ . b. Effect of caffeine on exogenous Friend leukaemia virus infection. Open symbols indicate treatment before infection and closed symbols after infection. Duplicate experiments are shown. Three dishes were used for each point. The mean plaque number in the control dishes was 125 and 109 for experiment 1 (○, ●) and experiment 2 (△, ▲), respectively.

submitted to the XC test. Figure 1a shows that caffeine treatment after IUdR treatment significantly inhibited virus induction; a proportional relation was observed between caffeine concentration and the inhibition of induction of the C-type virus. Treatment with doses of caffeine as high as 2.5 mM before IUdR treatment was almost without effect.

In order to test the effect of caffeine on the exogenous C-type virus infection, MLg cells were treated with caffeine (1.25 to 5 mM) for 24 h before or after infection with Friend murine leukaemia virus (adsorption for 2 h). Twenty-four hours after infection, 10<sup>3</sup> normal MLg cells were added per dish. Three days later, the XC test was performed. Figure 1b shows that caffeine was without effect on exogenous virus infection.

Various ways of inhibiting cellular DNA synthesis, such as treatment with arabinosyl cytosine, excess thymidine and serum starvation, have been reported to inhibit virus induction<sup>6</sup>. The inhibition was presumably due to inhibition of •IUdR incorporation. These conditions also inhibit exogenous C-type infection7,8; consequently, in some cases, propagation of the induced virus may be inhibited.

Since caffeine affects neither the exogenous virus infection nor incorporation of 128 IUdR (data not shown) caffeine may interfere with events specific to virus induction.

What happens between IUdR incorporation into the cellular DNA and the subsequent release of the induced virus is obscure. Excision of the viral genome may or may not be necessary. In any event, viral induction may be brought about by some toxic modifications of DNA by IUdR. It is possible that IUdR may induce local distortion of DNA as the halogenated pyrimidines when incorporated into DNA cause fragmentation or instability of DNA. Caffeine, known to interact with denatured but not with helical DNA<sup>9</sup>, may interact with such distorted regions of the DNA, so as to prevent viral gene activation. This last suggestion gains support from the fact that caffeine was especially effective after IUdR incorporation.

I thank Drs R. Latarjet and E. Moustacchi for discussions and advice.

### Isolation of an inhibitor protein of E. coli RNA polymerase from T7 phage infected cell

BACTERIOPHAGE T7 gene expression is under a unique transcriptional control. The 'early to late' switch in T7 development involves a switch from the host Escherichia coli RNA polymerase to the T7-coded enzyme (T7-specific RNA polymerase1), transcribing early mRNA and late mRNA, respectively, from two different regions of the T7 genome<sup>2</sup>. In addition to the gene 1 coding for T7-specific

RNA polymerase, this early-late switch requires the function of another early gene of T7, gene 0.7 or the 'host shut-off' gene<sup>2,3</sup>, to shut off the synthesis of host RNA and T7 early mRNA. This shut-off function is assumed to be an inactivation of the host RNA polymerase, although this has not been proven<sup>4,3</sup>. Furthermore, we have previously shown that T7 early mRNAs are functionally unstable, although they remain chemically stable late in T7 infection<sup>6,7</sup>. Thus, it seems that a complete switch of T7 gene expression from early to late involves at least three different control mechanisms. It has been shown that a T7-coded translational repressor may also play a role in the elimination of host functions<sup>6</sup>.

Here we report that the 'host shut-off' function is indeed an inactivation of the host RNA polymerase molecule, involving an inhibitor protein bound to the enzyme. When this inhibitor protein, here referred to as 'I' protein, is removed from the inactive host RNA polymerase prepared from T7 infected cells, the core enzyme and the sigma factor are both functionally active. The I protein, with a molecular weight of about 66,000, has been purified. It inhibits the host RNA polymerase holoenzyme, but does not inhibit the core enzyme or the T7-specific RNA polymerase.

Figure 1 shows the switch from the host RNA polymerase to the T7-specific enzyme in normal T7 infection. Cell-free extracts were prepared from T7 infected cells at the times indicated and assayed for the two enzymes. A rapid reduction of the host RNA polymerase activity coincided with a rapid increase of the T7-specific RNA polymerase activity. Since addition of rifampicin 5 min or later after T7 infection did not change the kinetics of appearance or the final yield of T7-specific RNA poly-

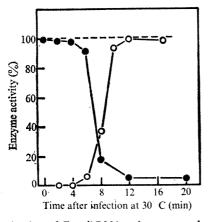

Fig. 1 Inactivation of E. coli RNA polymerase and appearance of T7-specific RNA polymerase after T7 infection. E. coli D10 F- (ref. 6) was infected with T7 phage at a multiplicity of infection of 5 at 30° C. Cells were also infected with T7 in the presence of chloramphenicol (150 µg ml<sup>-1</sup>) added 5 min before infection. Aliquots of the culture were withdrawn at indicated times and the cells were collected by centrifugation. The cells were suspended in a buffer containing 0.05 M Tris-HCl, pH 7.9, 0.01 M MgCl<sub>2</sub>, 0.15 M KCl, 1 mM dithiothreitol (DTT) and 0.1 mM EDTA and sonicated. Sonicated extracts were centrifuged at 12,000g for 10 min. Approximately 400 µg (protein) of the cell-free extract was used for the assay of *E. coli* RNA polymerase activity. The standard assay mixture<sup>19</sup> contained 5 µg T4 DNA in a total volume of 0.25 ml and was incubated at 37° C for 15 min. The sonicated cell-free extract was also used for the assay of T7-specific RNA polymerase activity following the method previously described<sup>1,7</sup>. The assay mixture contained 5.6 µg T7 DNA and 5 µg rifampicin in a total volume of 0.25 ml, and was incubated at 37° C for 10 min. Since rifampicin inhibits only E. coli RNA polymerase, this assay is specific for T7-specific RNA polymerase. Enzyme activities were normalised by measuring the protein content of each extract. The 100% values were: RNA polymerase, (--), E. coli RNA polymerase in the presence of chloramphenicol; (()), T7-specific RNA polymerase.

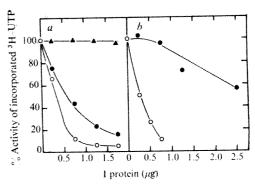

Fig. 2 Specific inhibition of *E. coli* RNA polymerase holoenzyme by I protein. *a*, Standard RNA-synthesising system<sup>19</sup> contained <sup>3</sup>H-UTP and 2.4 μg T4 DNA or 4.4 μg poly(dAT), and was incubated at 37° C for 15 min. Various amounts of purified I protein, electrophoretically more than 90% pure, were added to the reaction.  $\bigcirc$ , *E. coli* RNA polymerase holoenzyme (4.4 μg) on T4 DNA. The 100% value was 23,000 c.p.m. per reaction.  $\bigcirc$ , *E. coli* RNA polymerase holoenzyme (4.4 μg) on poly(dAT). The 100% value was 35,000 c.p.m. per reaction.  $\bigcirc$ , *E. coli* RNA polymerase core enzyme (3 μg) on poly(dAT). The 100% value was 45,000 c.p.m. per reaction. *b*, *E. coli* RNA polymerase holoenzyme was assayed as in *a* with 4.5 μg T7 DNA. T7-specific RNA polymerase was assayed as in Fig. 1, with 4.5 μg T7 DNA in the presence of rifampicin<sup>1-7</sup>. The actual molar amount of T7-specific RNA polymerase protein used was about one-twentieth of that of *E. coli* RNA polymerase. Increasing amounts of I protein were added. ( $\bigcirc$ ), *E. coli* RNA polymerase on T7 DNA. The 100% value was 26,000 c.p.m. per reaction. ( $\bigcirc$ ), T7-specific RNA polymerase on T7 DNA. The 100% value was 27,000 c.p.m. per reaction.

merase<sup>7</sup>, we assume that no new initiations of T7 early mRNA transcription by the host RNA polymerase occur after this time (T7-specific RNA polymerase is one of the early gene products<sup>2</sup>). This shut-off of T7 early mRNA synthesis, probably concomitant with the shut-off of host RNA synthesis, parallels with the decline of the host RNA polymerase activity (Fig. 1). When the cells were infected with T7 in the presence of chloramphenicol, no reduction in the activity of the host RNA polymerase was observed, indicating that protein synthesis after T7 infection is required to accomplish the shut-off function.

The result shown in Table 1 was obtained after removing endogenous DNA from sonicated cell-free extracts by DNase treatment. DNase-treated extracts were centrifuged in glycerol gradients and the lower portions of the gradients, containing the host RNA polymerase activity but free of DNase activity, were pooled and assayed for RNA synthesis on T4 phage DNA and poly(dAT) templates. The crude enzyme from uninfected cells exhibited an activity of above 1.2 on T4 DNA relative to that on poly(dAT) and this activity ratio, T4 DNA: poly(dAT), reached about 2.0 after purification. The crude host enzyme from T7 infected cells however, showed an activity ratio of only about 0.2. A considerable activity on poly(dAT) in the enzyme from T7 infected cells was used to monitor its recovery during purification. The presence of chloramphenicol prevented the reduction of the host RNA polymerase activity in T7 infected cells (Table 1).

The E. coli RNA polymerase was purified from uninfected control cells and T7 infected cells harvested 9 min after infection, using essentially the same procedure described by Burgess. After the first glycerol gradient purification step in the absence of KCl, the control enzyme showed an activity ratio on T4 DNA against poly(dAT) of between 1.5 and 2.0, whereas the enzyme from T7 infected cells showed a ratio of about 0.2. After the second glycerol gradient step in the presence of 1 M KCl, the relative activity on T4 DNA and poly(dAT) of the control enzyme was about 2.0, while the enzyme from T7 infected cells displayed a value about 1.0. The increased activity of the enzyme from T7 infected cells on T4 DNA after

the second gradient step was due to a partial removal of inhibitory material. When gradient fractions sedimenting more slowly than the enzyme were added back to it, its relative activity on T4 DNA and poly(dAT) was about 0.2, the same as that before the second gradient step.

The purified enzymes, after the second gradient step, were analysed by electrophoresis in polyacrylamide-SDS slab gels. The enzyme from T7 infected cells contained, in addition to  $\alpha$ ,  $\beta$ ,  $\beta'$  subunits and sigma factor, two protein components which were usually absent in the control enzyme and when present, only in a trace amount. One protein component tentatively termed as I has been purified as described below, and found to be an ihibitor of the host RNA polymerase. The other protein migrating slightly faster than the I protein has also been purified, but has no effect on the RNA polymerase activity.

The RNA polymerase from T7 infected cells recovered full sigma and core enzyme activities when the inhibitor protein I was completely removed. This was shown by subjecting the host RNA polymerase from T7 infected cells to phosphocellulose column chromatography. The protein I was separated from the enzyme complex and eluted in the flow-through. The sigma factor and core enzyme were also separated. Sigma factor was further purified by DEAE column chromatography and glycerol gradient centrifugation. The purified sigma factor and the core enzyme eluted from the phosphocellulose were electrophoretically more than 95% pure. Reconstitution experiments showed that purified sigma factor and core enzyme from T7 infected cells are functionally normal in forming fully active RNA polymerase holoenzyme both with each other, and with samples purified from uninfected cells.

The I protein was purified from the flow-through of the phosphocellulose column and by DEAE cellulose column chromatography followed by glycerol gradient centrifugation. Purified I protein moved slightly faster than bovine serum albumin in electrophoresis in the presence of SDS and its molecular weight was estimated as about 66,000. In some cases it was purified from the enzyme preparation after the first glycerol gradient, because at this step the enzyme contained more I protein than after the second

Figure 2a shows the inhibition of E. coli RNA polymerase holoenzyme by purified I protein. RNA synthesis on T4 DNA was inhibited almost completely at a molar ratio of I to enzyme of about 1. The holoenzyme acivity on poly(dAT) was also inhibited by I, but to a slightly lesser extent. No inhibition was observed when I protein was added to the core enzyme synthesising RNA on poly(dAT). Figure 2b also shows the inhibition of the holoenzyme by purified I protein in T7 DNA-directed RNA synthesis. At a concentration of I protein (0.75  $\mu$ g) which inhibited the host RNA polymerase by 90%, T7-specific RNA polymerase was not inhibited. At higher I protein concentrations, T7-specific RNA polymerase was somewhat inhibited. Because the molar amount of T7-specific RNA polymerase used in the reaction was about one-twentieth of that of the host enzyme, however, at these concentrations of I protein the ratio of I to the T7-specific RNA polymerase was very high.

These results indicate that the inhibition by I protein is specific for the host RNA polymerase holoenzyme and that the presence of sigma factor is required for this inhibition. The details of the interaction between I protein and the holoenzyme are under investigation. Since the core RNA polymerase of the host and the T7-specific RNA polymerase both synthesised normal amounts of RNA in the presence of I protein, at a concentration which effectively inhibited RNA synthesis by the host holoenzyme on the same templates (Fig. 2), I protein does not seem to have DNase or RNase activity. Also, T7 DNA-directed RNA synthesis by the host holoenzyme was inhibited by I protein

to a similar extent as shown in Fig. 2b even when four times more T7 DNA was added as template. This result suggests that DNase activity in I protein is unlikely and supports the idea that I protein interacts with the holoenzyme rather than with the DNA template.

We have not yet determined whether I protein is directly coded by T7, or is instead a host protein somehow activated or induced by T7 infection. It is certain, however, that protein synthesis after T7 infection is required to manifest the inactivation of the host RNA polymerase by I protein, since the presence of chloramphenical permits the host RNA polymerase to remain fully active (Fig. 1, Table 1). If I protein is coded by T7, the most likely

Table 1 E. coli RNA polymerase activity after T7 infection

Conditions of T7 infection	Activity on T4 DNA (%)	Activity on poly(dAT)	Ratio* T4 DNA poly(dAT)
Uninfected 9 min after infection	100† 17	100† 43	1.271 0.21
9 min after infection, (With chloramphenicol)	98	specific to	

Sonicated cell-free extracts, prepared as in Fig. 1, were treated with 150 µg ml<sup>-1</sup> DNase at 0° C for 15 min and centrifuged at 20,000g for 15 min. The extract was layered on a 15-30% glycerol gradient in 12 ml containing 0.01 M Tris-HCl, pH 7.9, 0.01 M MgCl, 0.15 M KCl, 1 mM DTT and 0.1 mM EDTA, and centrifuged at 200,000g for 12 h. Aliquots (40 µl) of pooled bottom two-third fractions were assayed as in Fig. 1, with the addition of 3.4 µg T4 DNA or 4.0 µg of assayed as in Fig. 1, with the addition of 3.4 µg T4 DNA or 4.0 µg of

poly(dAT).

\*In the activity ratio calculation, it was assumed that UMP appears twice as frequently in poly(dAT)-directed RNA as in T4 DNAdirected RNA. Therefore, the ratio is (pmol UMP in T4 RNA/mg protein × 2): (pmol UMP in poly AU/mg protein). †100% values were: 8,700 c.p.m. for T4 DNA, and 13, 700 c.p.m. for

poly(dAT). ‡Highly purified enzyme from uninfected cells usually showed a ratio

candidate is the 'host shut-off' gene (gene 0.7) as has been suggested3-5. Gene 0.7 transcribes mRNA of molecular weight 650,000 (refs 3 and 10), large enough to code for a protein of the size of I (molecular weight 66,000). The protein product of gene 0.7 is however known to have a molecular weight of only 40,000 although a precursor molecule of larger size may exist3. It is interesting that the product of gene 0.7 was recently shown to be a protein kinase which phosphorylates many host proteins<sup>11</sup>. The possibility that I is a host protein cannot be ruled out. Indeed a protein similar to I in electrophoretic mobility was detectable, although in small amounts, in the RNA polymerase preparations from uninfected cells. It is also possible that gene 0.7 exerts 'host shut-off' function through the protein phosphorylating activity thereby directly or indirectly mobilising I protein.

With the closely related phage T3, a protein which inhibits the host RNA polymerase has been reported12,13 Although this T3 protein seems to be controlled by a late gene, we cannot make a good comparison with I protein because the T3 protein has not been purified.

We have found in addition that I protein also inhibits in vitro translation of MS2 RNA. Figure 3 shows that I protein inhibited MS2 RNA-directed met-tRNA binding to ribosomes (Fig. 3a) and phenylalanine incorporation into protein (Fig. 3b). Using 1.5 µg I protein and 5 µg MS2 RNA, about 50% inhibition was achieved in both cases. Increasing amounts of MS2 RNA reduced the inhibitory effect of I protein; 10 μg of MS2 RNA required about 3 μg of I protein to be inhibited to the same extent. On the other hand, I protein did not inhibit in vitro translation (measured as above) of T7 early mRNA prepared from ultraviolet-irradiated, T7 gene 1-amber mutant phageinfected cells following the procedure described previously\*. These characteristics are very similar to those of a cistron-

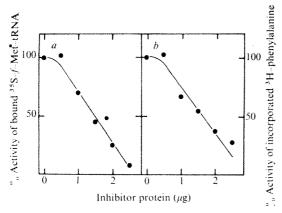

Fig. 3 Inhibition of in vitro translation of MS2 RNA by I protein. RNA-directed f-met-tRNA binding to ribosomes. The initiation factor-dependent reaction was carried out as described previously<sup>8</sup> and contained 5 µg MS2 RNA, 75 µg NH<sub>4</sub>Cl-washed ribosomes, 20 µg crude initiation factors and 3.5 × 10<sup>5</sup> c.p.m. <sup>35</sup>S-labelled *f*-met-tRNA. Various amounts of purified I protein were added as indicated. The reaction was at 35° C for 15 min. The 100% value was 52,159 c.p.m. per reaction. b, MS2 RNA-directed phenylalanine incorporation into protein. A standard in vitro protein-synthesising system<sup>6</sup>. It was confirmed that the major products of this reaction were MS2 coat protein and RNA replicase, by gel electrophoresis<sup>20</sup>. The reaction was at 37° C for 15 min and contained 5 µg MS2 RNA, 10 µCi per 2 nmol <sup>3</sup>H-phenylalanine and various amounts of purified 1 protein. The 100% value was 37,517 c.p.m. per reaction.

specific translational control protein, 'i' factor, which is also one of the host-coded subunits of Q<sub>B</sub> phage RNA replicase (refs 14-18) and is probably identical with the E. coli 30S ribosomal protein, S1 (cited in ref. 16). The 'i' factor binds to the RNA of RNA phages MS2 (refs 14 and 15) and R17 (refs 16-18), and specifically inhibits translational initiation of the coat protein cistron, but it does not inhibit in vitro translation of T4 mRNA or endogenous E. coli mRNA. But 'i' factor seems to have a slightly larger molecular weight (74,000) than the I protein described here. Further investigation is in progress concerning the translational inhibition by I protein and its identity.

### Biological decay of the 5'-triphosphate termini of the RNA of E. coli

EXPERIMENTS in vitro and in vivo have shown that nascent RNA chains have 5'-triphosphate termini and that the 5' terminal nucleosides are either adenosine or guanosine1-3. Little is known about the fate of these termini. It is known that in Escherichia coli mRNA is degraded rapidly4, and that the nascent precursors of ribosomal and tRNA mature—a process involving trimming at the 5' end<sup>3-7</sup>—and then have only one phosphate group on the 5' end7,8. It seems, therefore, that the 5'-triphosphate termini should disappear as a result of mRNA decay and stable RNA maturation. We have examined the disappearance of triphosphate termini from E. coli RNA and found that they decay at a rate approximately one-half of that of the bulk of the unstable RNA.

We followed the decay of 32P-labelled triphosphate termini in cell cultures after rifamycin SV had been added to stop further initiation of RNA synthesis9. Since E. coli is relatively resistant to rifamycin, we used the mutant strain E. coli H-101 (ref. 10), which is sensitive. To determine whether there was a lag in rifamycin action and how completely it blocked RNA synthesis, a control experiment on induction of the lactose operon was performed. This was similar to that done with strain AS 19 (ref. 11), except that adenosine-3',5'-cyclic monophosphate was added to avoid the effects of catabolite repression<sup>12</sup>. Cells were induced with isopropyl-β-D-thiogalactopyranoside at various times before and after addition of rifamycin, protein synthesis was allowed to continue for 20 min, and

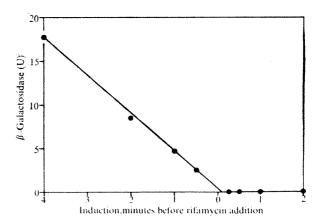

Fig. 1 Inhibition of induction of  $\beta$ -galactosidase synthesis was added to each of 10 flasks containing 1 ml of 0.015 M adenosine-3',5'-cyclic monophosphate (neutralised to pH 7.0) and 0.2 ml of 6 x growth medium. Cells were induced by addition of 0.3 ml of 0.01 M IPTG at various times before or after the addition of 0.6 ml of 500  $\mu$ g ml<sup>-1</sup> of rifamycin SV. Twenty minutes after induction, cells were treated with toluene, and  $\beta$ -galactosidase was assayed by the method of Abbo and Pardee<sup>20</sup>.

 $\beta$ -galactosidase activity was assayed (Fig. 1). The results of this control show that initiation of RNA synthesis was shut off within 15 s of the addition of 100  $\mu$ g ml<sup>-1</sup> of rifamycin.

Decay experiments were performed as follows. Cells, growing at 37°C, were labelled with 32P-phosphate for 5 min, and rifamycin SV was added to stop further initiation of RNA synthesis. Culture samples were taken immediately after rifamycin addition and during the next 16 min. The samples were each mixed with a given volume of cells from a culture labelled with 3H-guanine, to give an internal standard on RNA recovery in the purification steps. RNA was then isolated from the culture samples (see legend to Fig. 2) and purified on gel filtration columns. (This purification was necessary due to the accumulation of 32P-labelled contaminants, presumed to be polyphosphates, which interfere with the detection of the pppNps.) The purified RNA samples were hydrolysed with KOH, releasing adenosine-2'(3')-monophosphate, 5'-triphosphate (pppAp), and guanosine-2'(3')-monophosphate, 5'-triphosphate (pppGp) from the triphosphate termini<sup>13</sup>. There compounds were identified by DEAE paper electrophoresis at pH 3.9 as already described13. 32P was counted in a liquid scintillation counter and corrected to a reference date for radioactive decay.

We performed two experiments on the decay of triphosphate termini, differing in the purification of the RNA by gel filtration. In the first experiment, RNA was purified on a Bio-Gel P-10 column (exclusion approximately 20,000 daltons), retaining the excluded vol-

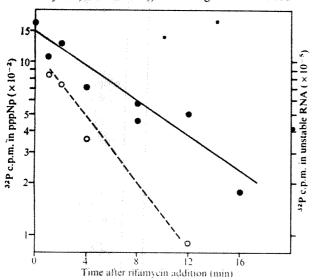

Fig. 2 Radioactivity in RNA (○) and in pppNps (●) after rifamycin treatment. Cells were grown at 37° C in glucose minimal medium³, using HEPES buffer and supplemented with 100 μg ml⁻¹ of methionine. They were grown to an optical density (at 540 nm, 1 cm path) of 0.8, washed with low phosphate medium, shifted to low phosphate medium (2×10⁻³ M phosphate), incubated for 3 min, and pulse labelled with 50 mCi of ³²P-phosphate for 5 min. At the end of this labelling time, rifamycin SV and non-radioactive phosphate buffer (pH 6.8) were added to the culture to make final concentrations of 300 μg ml⁻¹ rifamycin and 10⁻³ M phosphate. Culture samples were taken at various times and mixed with equal amounts of ³H-guanine labelled cells. Cells were broken open in 2% sodium dodecyl sulphate at 60° C and RNA was isolated by phenol extraction, ethanol precipitation and purification on Bio-Gel P-10 (Biorad) gel filtration columns at 4° C. The excluded RNA fractions were then hydrolysed with KOH and the residual DNA and protein were precipitated with perchloric acid¹³. Samples were absorbed on charcoal and eluted with ethanol: 28% NH.OH: H-O (66:2:32). The total ³²P counts in purified ribonucleotides were taken as total RNA and the ³²P counts in pppNps as total triphosphate termini (adjusted by ³H-guanine nucleotide recovery). The data for the decay of RNA were corrected by the subtraction of the stable RNA fraction (that remaining after 16 min).

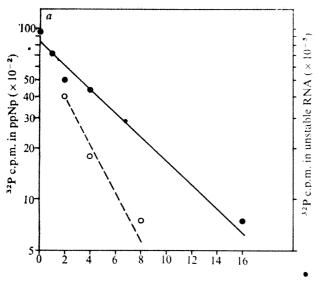

ume for analysis. The data show total 32P c.p.m. in the RNA and in the triphosphate termini as mononucleotides and pppNps released by KOH hydrolysis of that RNA (Fig. 2). The second experiment was similar, except that RNA samples were divided in half, and each half was run on a separate Sephadex G-100 column. eluates from these columns were separately pooled to include both the excluded peak and the material eluting up to a K<sub>av</sub> (ref. 14) of 0.48. Calibration of similar columns, using single-stranded DNA fragments of known length, by Dr Donald A. Kaplan, indicates that this material includes oligomers of length approximately 12 and greater. The data for the second experiment shows 32P c.p.m. in RNA, in total pppNps released by KOH hydrolysis, and also in pppAp with results from duplicate samples given to indicate the variability encountered in these experiments (Fig. 3). Further data, not given, show that the ratio of 32P c.p.m. in pppGp to pppAp at the beginning of each experiment was 1.4 and that this did not change significantly throughout the experiments. Thus the kinetics for the decay of both guanosine and adenosine triphosphate termini were similar.

The data for the decay of RNA and triphosphate termini from these experiments can be approximated by exponential decay as seen by the straight lines drawn on the semi-logarithmic graphs. These approximations give halflives of 3.4 and 6.0 min for the decay of the RNA and triphosphate termini respectively in the first experiment, and 2.1 and 4.6 min in the second experiment. Using a different method, Konrad estimated the halflife of the termini at 21.5° to be at least 170 s (ref. 15).

In interpreting these data, we assume either that the 5' ends of all species of nascent RNA are destroyed by the same mechanism or that the data reflect primarily the decay of a particular species of RNA, presumably the messenger. Preliminary work done in this laboratory by Charles Bieger, indicates that a significant proportion of the 32P-labelled triphosphate termini on E. coli RNA after a 5 min pulse with 32P-phosphate is found in polysomes; however, the exact amount depends on the method of extraction of the cells. If tRNAs were made monocistronically, one would expect their precursors to contribute the majority of triphosphate termini in the E. coli cell because these termini are a measure of the number and not the weight of RNA molecules13. There is, however, an indication that some tRNAs are made polycistronically\*, and thus their contribution to the 5' termini will be reduced. Furthermore, as the nascent tRNA precursors are undetectable in normal cells growing at 37° C, their termini may disappear extremely rapidly. Finally, the dreav of triphosphate termini seen in these experiments could be the result of one of two processes. The 5' end of the RNA could be degraded so that the triphosphate termini would be on a small polynucleotide, for example, less than 12 nucleotides long in our second experiment, or by a process whereby one or more of the phosphates are removed from the triphosphate termini.

Our data rule out the possibility that the triphosophate termini decay much faster than does unstable RNA. In fact the decay of the former could be a result of the decay of the latter. Since the data indicate a longer half life for the decay of triphosphate termini than for that of unstable RNA, they suggest that degradation of triphosphate termini occurs by a separate mechanism than that primarily responsible for the degradation of RNA.

From the results of work on the decay of both lactose mRNA and tryptophan mRNA, Kennell et al. concluded that each cistron in these polycistronic RNAs has a unique site that is vulnerable to attack, causing inactivation. This attack is presumably the initial event in the breakdown of the message<sup>4,18</sup>. From work on the decay of tryptophan mRNA, Yanofsky et al. make a model for the

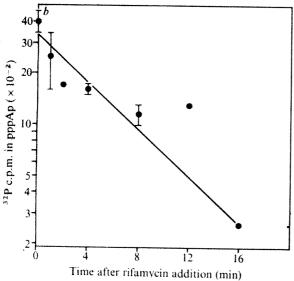

Fig. 3 Radioactivity in RNA (()) and in pppNps (()) after rifamycin treatment. The experiment was performed as described for Fig. 2, except that the RNA was purified on Sephadex G-100 (Pharmacia) columns as described in the text. a, <sup>32</sup>P c.p.m. in RNA and in total pppNp; b, <sup>32</sup>P c.p.m. in pppAp. Upper and lower brackets show data from duplicate columns.

decay of mRNA in which the initial degradative event occurs near the 5' end of the molecule and is followed by degradation in the 3' direction17. We favour a model where internal degradation is the first step in mRNA decay. Such a model is supported by the discovery of 5'-terminal fragments of the transcripts of the T7 early-genes and tryptophan operon<sup>18,19</sup>. The longer half life of the 5' terminus could be the result of the presence of the triphosphate termini inhibiting a 5'-exonuclease attack. Alternatively, if messenger degradation is associated with translation, the 5' end of the molecule, which is not translated, would be degraded by a separate mechanism.

### Model for wandering restriction enzymes

I wish to propose a model for those DNA restriction enzymes which, although requiring specific recognition sites, make a limited number of cuts at apparently random sites, far from the recognition sites.

Many bacteria have restriction and modification enzymes which recognise and attack DNA from other organisms (for recent reviews see refs 1, 2 and 3). A modification enzyme recognises a particular nucleotide sequence and modifies it, for example, by methylating a nucleotide in this sequence. DNA from other organisms, lacking this modification, is recognised as foreign, and is cut by a restriction enzyme. On the other hand, DNA which has been modified or which does not include the recognition sequence is not cut, that is, it is not restricted. Both strands of DNA are usually modified. Replication of modified DNA yields DNA of which one strand (the parental) is modified, and the other (the daughter) is unmodified. Modification in only one strand prevents restriction but permits modification of the other strand. In this way DNA can replicate without becoming sensitive to restriction.

Restriction enzymes fit into two groups on the basis of their restriction products. Enzymes of group I, such as those of Haemophilus4 and those encoded by the RI5 and RII6 resistance transfer factors, cut at unique sites of the DNA yielding a population of specific fragments7-9 with unique terminal sequences. The terminal sequences, where known, imply that the nucleases act at symmetric DNA nucleotide sequences<sup>4-6</sup>, that is sequences such as

5' . . . pGpTpTpApApCp . . . 3' 3'...pCpApApTpTpGp...5'

which reads the same from left to right as from right to left. This sequence, a substrate of a *Haemophilus* enzyme<sup>4</sup>, consists popipi ) arranged symmetricof two identical components (pGpTpT

Within a symmetric sequence both strands look alike. A modification or restriction enzyme which recognises part or all of the sequence could act on both strands, either sequentially, first on one strand and then on the other, or, if the enzyme were a symmetric dimer, simultaneously on both strands.

Restriction enzymes of group II, those of Esherichia coli<sup>10-12</sup> and phage P1 (unpublished results of K. Horiuchi, quoted in ref. 13), recognise specific sites, but in contrast to group I enzymes they make a limited number of double strand cuts at

apparently random sites, far from the recognition sites. For example, the circular DNA molecule that is the replicative form of phage f1 is cut only once by the *E. coli* B restriction enzyme, yielding a linear molecule which is resistant to further degradation. The cuts generate a heterogenous population of molecules which can be denatured and renatured to reform circular molecules. These circular molecules, in contrast to the linear molecules, are again sensitive to the restriction nuclease, indicating (1) that the recognition sites are not inactivated by the first cut, and (2) that a circular molecule is necessary for the recognition sites to be effective<sup>11</sup>.

A puzzling feature is the difference between the number of cuts introduced and the number of recognition sites. Phage fl has two widely separated recognition sites (denoted sB<sub>1</sub> and sB<sub>2</sub>) which render the phage DNA sensitive to the *E. coli* B restriction nuclease<sup>14</sup>. In vivo, phage bearing mutations in either sB<sub>1</sub> or sB<sub>2</sub> are partially resistant to restriction, and phage carrying both mutations are completely resistant. Although the presence of either recognition site permits a cut by the restriction nuclease, the two sites together do not permit two cuts<sup>11</sup>.

Figure 1 depicts a model for the action of group II restriction nucleases. Suppose that a specific asymmetric (unmodified) recognition sequence permits binding of the nuclease<sup>12,15</sup>. Having bound, the enzyme now wanders (in the direction defined by the orientation of the recognition site) along the DNA until it meets a nuclease which started from an oppositely oriented sequence. A meeting, head to head, is the signal to cut the DNA. The cutting might occur at many different sites, depending on where the nucleases meet. Once the first double strand cut is introduced, enzymes starting from these recognition sites would no longer be able to meet, accounting for the resistance of the linear molecule to further cutting.

In this model the complete recognition site might be viewed as comprising two identical nucleotide sequences arranged in opposite orientations. The stretch of DNA between the two components of the recognition site might be thousands of

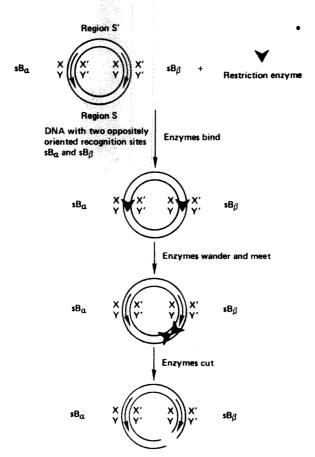

Fig. 1 Model proposed for group II restriction enzymes.

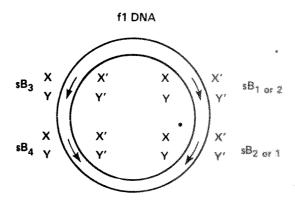

Fig. 2 Proposed arrangement on phage f1 DNA of the recognition sites of the restriction modification system of E. coli B.

nucleotides (the case of phage f!)<sup>11</sup> or only a few nucleotides in which case the restriction enzyme would seem to act like a group I enzyme.

The complete recognition site, composed of two oppositely oriented identical sequences is symmetric. Whereas for group I enzymes, the two components of the symmetric recognition region are juxtaposed, for group II enzymes the two components can be separated by a long and variable nucleotide sequence, and the nuclease can act anywhere in this nonspecific sequence.

Modification (methylation) of the DNA of phage fd (perhaps identical to phage f1) is blocked by mutations at sites sB1 and sB<sub>0</sub><sup>16</sup>, suggesting according to this model, that modification of the putative sites sB<sub>3</sub> and sB<sub>4</sub> depends on the sites sB<sub>1</sub> and sB<sub>2</sub>. The modification enzyme might bind at the recognition site of one strand and wander to a recognition site in the other strand, which it would then modify, thus blocking the binding of restriction enzyme and protecting the DNA. Two oppositely oriented recognition sites would be required for modification activity, as for restriction activity. The type of interaction between the modification enzyme and recognition site would depend on how each component is presented. Free enzyme would bind to but not modify a recognition site. Wandering enzyme would modify a recognition site presented in the orientation opposite the orientation of the site to which that modification enzyme had bound.

The restriction nuclease might also interact differently with the two components of the recognition site. According to the version presented in Fig. 1, the restriction nuclease might bind at one recognition site and wander past the complementary site, finally encountering the complementary nuclease in the region S'. Cutting in the region S' should not preclude cutting in the region S. Only one cut is observed, however, for f1 DNA, suggesting that the restriction nuclease cannot pass a recognition site, perhaps because of the particular experimental conditions used, or perhaps because wandering restriction nuclease specifically interacts with a recognition site to obviate further wandering.

I thank Max Gottesman for criticism and Martha Harshman for preparing the manuscript. This work was supported by the Centre National de la Recherche Scientifique and the National Institutes of Health.

### C-type viruses in systemic lupus erythematosus

VIRUSES have been implicated as the agents of systemic Jupus erythematosus (SLE) expressed by dogs' and mice<sup>2</sup>. We have shown that cell-free filtrates prepared from the spleens of dogs with positive LE cell tests induced antinuclear and anti-double-stranded DNA antibodies in CAF mice. The canine filtrate also induced lymphoid tumours in some recipient mice<sup>1</sup>. One of these neoplasms, SP 104, produces a monoclonal antibody against double-stranded DNA. Cultured SP 104 cells produce, in addition to the anti-DNA antibody, C-type RNA viruses that induce antinuclear antibodies when inoculated into normal mice (R.M.L., W.T., C.S., and R.S.S., unpublished). Here we present preliminary evidence linking the SP 104 virus to SLE in humans. Our results suggest that antigenic determinants related to the SP 104 virus are present on the lymphocytes of patients with SLE.

An antibody to the SP 104 virus was made in rabbits using purified C particles that were isolated from the fluid of cultured SP 104 cells by isopycnic centrifugation3 through a 15-60% sucrose gradient. The virus had a buoyant density of 1.16 and all the reverse transcriptase activity of the preparation was localised to this band of the gradient. The banded virus contained 70S RNA, behaved as a B-tropic MuLV in the XC plaque assay, contained the gs-1 antigen of MuLV, had a PI of 3.2 by isoelectric focusing and by electron microscopy consisted almost entirely of C-type particles.

The purified virus was disrupted with ether and injected into New Zealand rabbits. Ten days after two subcutaneous injections of the virions, serum was collected and absorbed sequentially with foetal calf serum, normal murine (CAF<sub>1</sub>) spleen cells and blood lymphocytes from normal human subjects. By gel diffusion analysis, a single line of identity was obtained when purified undisrupted and ethertreated SP 104 virions were reacted with the absorbed serum. The absorbed serum failed to react with DNA in gel diffusion tests and did not bind to 3H-labelled DNA in a sensitive radioimmunoassay for anti-DNA antibodies3. Neither antinuclear antibodies nor antibodies against human or murine serum proteins or cell membrane were detectable in the rabbit serum.

A globulin-rich fraction of the absorbed serum was prepared by ammonium sulphate precipitation. The final product reacted with SP 104 virions in gel diffusion and failed to react in any of the above mentioned tests. The globulins were then conjugated to fluorescein isothiocyanate in a molar ratio (fluorescein: protein) of 10:1 (ref. 7). Lymphocytes, separated from the blood of subjects by centrifugation through a Ficoll-Hypaque gradient<sup>6</sup> and further purified by removal of phagocytes8, were incubated with the conjugate, washed, fixed in ethanol and examined by dark field fluorescence microscopy. The lymphocytes of normal subjects failed to react with the conjugate. By contrast, typical and brilliant membrane fluorescence was observed on the lymphocytes of five out of six patients with SLE. The number of lymphocytes stained by the conjugate ranged from 46×10<sup>s</sup> to 400×10<sup>s</sup> cells. Individual values for the patients studied were 0, 46, 149, 181, 195, and 400. These figures were obtained by examining at least 200 cover slip fields, each of which contained between 400 and 800 lymphocytes. Independent experiments performed on the same cell preparations by two of us gave results that agreed within a margin of 20%. Normal rabbit globulins, treated in the same way, failed to react with any of the lymphocytes.

We next sought evidence in a patient with SLE of an antibody with reactivity similar to that of the rabbit anti-SP 104 virus antibody. A 12-yr-old girl (DeV) was selected as a subject because she had active, untreated SLE with multisystem involvement. Her serum was treated with ammonium sulphate, conjugated to fluorescein isothiocyanate, and used to stain the blood lymphocytes of various subjects in the same manner as the rabbit serum. DeV's serum failed to bind to the cytoplasmic membranes of lymphocytes from either six normal subjects or from six patients with diseases other than SLE. By contrast, typical membrane staining was found with the lymphocytes of eight out of ten patients with SLE (Table 1). The number of lymphocytes stained by the conjugate ranged from 6×10° to 650×10° lymphocytes, a proportion similar to that observed with the rabbit antiserum. Raising the temperature of the reaction mixture to 37° C for 30 min (following incubation at 4°C) resulted in polar capping of the fluorescent stain. The reactivity of the DeV reagent was abolished by previous incubation with a monospecific rabbit anti-human IgG serum, but not by incubation with a rabbit anti-human fibrinogen serum. Immunoglobulins prepared in the same way from normal human serum did not bind to any of the lymphocytes of five patients with SLE.

The immunoglobulin fraction of DeV's serum was absorbed with pelleted C-type particles obtained from the SP 104 culture. The absorbed material, after conjugation to fluorescein isothiocyanate, failed to stain the lymphocytes of five out of eight patients with SLE. In a seventh patient (T.O.U.), absorption of DeV's serum with C-type particles reduced the reaction by about 90%. Absorption of the DeV conjugate with a suspension of 600×106 normal murine spleen cells failed to diminish its reaction with lymphocytes of patients with SLE. Moreover, the DeV conjugate failed to stain the cytoplasmic membranes of normal murine spleen cells. Removal of all anti-DNA antibodies by absorption of the conjugate with double- and single-stranded DNA also failed to diminish its ability to bind SLE lymphocytes, except in two cases, which are discussed presently. In a preliminary experiment, we also found that absorption with yeast (single-tranded) RNA and poly(I)-poly(C) (doublestranded RNA) also failed to remove the activity of DeV's serum against SLE lymphocytes.

Three of the eight patients we tested (L.E.V., F.A.Z., and T.O.U.) differ from the others in that they were clinically ill when their lymphocytes were examined; that relatively large numbers of their lymphocytes reacted with the DeV conjugate, the anti-SP 104 virus serum, or both; that absorption of this reactivity by the SP 104 virus was incomplete and that absorption by DNA removed some of the activity (F.A.Z., and T.O.U.). These results indicate that more than one SLE-related antigen may

SP 104, the pellet containing C-type virus particles; D-DNA, double-stranded DNA; S-DNA, single-stranded DNA.

appear on the membranes of circulating lymphocytes during the acute phase of the illness.

The antibody we detected in DeV's serum is not the anti-lymphocyte antibody described in SLE (ref. 9), nor is it an anti-IgG that stains B cells10 since it does not react with normal lymphocytes. We have tried to stain PHAtransformed lymphocytes from normal subjects with the DeV reagent, but no reaction was detected. The activity is not due to an antibody against the Epstein-Barr virus as no anti-EBV activity in DeV's serum has been found. Moreover, the determinant on the test lymphocyte is not an anti-IgG that might bind to the DeV reagent's because conjugated normal IgG did not react with the cells. We do not know if DeV's serum is unique; tests with the sera of other patients with SLE are in progress.

It seems that the lymphocytes of patients with SLE express an antigenic determinant shared by C-type RNA viruses produced by the SP 104 tumour. This plasmacytoma, we stress, also produces an antibody against double-stranded DNA; such antibodies are characteristic of SLE. Experiments are now under way to determine if the SP 104 virus is unique in its relationship to SLE. Our results do not exclude a virus-induced cellular antigen. Results with the rabbit antibody, however, which is directed against purified virus, suggest the presence of a virion determinant on the cytoplasmic membranes of lymphocytes of patients with SLE

### Rapid in vivo assay for murine lymphatic leukaemia viruses

SEVERAL rapid in vitro methods1-5 for the quantitative assay of murine lymphatic leukaemia viruses (MuLV) have replaced the once standard in vivo bioassay for leukaemogenicity8,7, which was slow, cumbersome, and relatively costly. The in vitro procedures, however, suffer from two limitations: first, some MuLV propagated serially in vitro may lose leukaemogenicity while retaining infectivity in vitro\*, so the in vitro assays do not necessarily correlate with biological activity invivo; second, some wild-type MuLV extracted from normal or neoplastic tissues in vivo seem to require a period of adaptation to in vitro growth conditions before they can be assayed reliably by in vitro methods9.

Both of these limitations apply to the radiation leukaemia virus (RadLV), a naturally occurring MuLV consistently extractable from thymic lymphomas induced in strain C57BL mice by whole-body X-irradiation, which induces thymic lymphomas after inoculation into neonatal or infant C57BL/Ka mice (in vivo-derived wild-type RadLV)6,16. It can also be propagated on mouse embryo fibroblasts8 and collected from the supernatant of permanently infected cultures (in vitroderived RadLV, designated RadLV\*). Several of the rapid • in vitro assay methods have recently been adapted to the titration of RadLV\* (refs 9, 11 and 12 and A.D., O.N., E. Gerlmann, and H.S.K., unpublished). Here we report a rapid in vivo endpoint dilution assay for wild-type RadLV which compares in sensitivity with in vitro endpoint dilution methods, correlates well with leukaemogenicity bioassays, and should be equally applicable to the in vivo assay of other thymotropic MuLV in their susceptible host strains.

C57BL/Ka mice of both sexes were used at 4-5 weeks of age. Wild-type preparations of RadLV were extracted from RadLVinduced lymphoma tissue by a previously described procedure18. Serial five-fold dilutions of virus in medium containing Polybrene (Abbott Laboratories), 4 µg ml<sup>-1</sup>, were injected in a volume of about 0.02 ml per lobe into one or both thymic lobes of groups of test mice14. A group of mice was also injected intravenously with 0.2 ml of serially diluted virus. Thymus cell suspensions were prepared at serial time intervals thereafter. Mice were killed with ether. The thymus was dissected free, minced in a small Petri dish, and passed through nylon cloth into (0.175 M NaCl) saline. Cells were kept in suspension on ice, and their concentration was adjusted to  $1 \times 10^6$  cells ml $^{-1}$ .

Indirect immunofluorescence (IF) staining of acetone-fixed cells for the detection of MuLV antigens was carried out as described by Hilgers et al.4 and adapted to virus titration

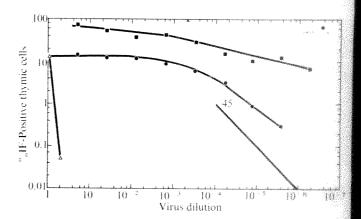

Fig. 1 Titration curves for serial dilutions of RadLV injected intrathymically into one ( ) or both ( ) lobes of the thymus, or injected intravenously (A). A 45° slope curve is included for comparison.

<sup>\*</sup> Not tested.

in vitro by Declève et al.9. The percentage of IF-positive cells recorded in each assay was that observed at the highest concentration of rat anti-serum yielding fluorescence specific for virus-related antigens<sup>4,9</sup>. Counts of 100-200 total cells suffice when IF-positive cells are abundant; conversely, fields containing 20,000 or more cells may be scanned to detect low frequencies of IF-positive cells. Direct examination of thymic lymphoid tissue for viral antigens by immunofluorescence was found to be straightforward, since no nonspecific reaction with immunoglobulin-bearing lymphoid cells could be detected in the normal rat serum or saline controls.

After direct intrathymic (IT) injection of RadLV into one thymic lobe, virus-related antigens were first detected at 7 d for RadLV dilutions ranging from  $5^{\circ}$  to  $5^{-7}$  (Table 1). At 14 d after inoculation, 3 of 11 mice were positive at the  $5^{-8}$  dilution, and 0 of 10 at the  $5^{-9}$  dilution, yielding an endpoint titre of  $3.9 \times 10^{5}$  per 0.02 ml. When the percentage of IF-positive cells observed on day 7 after inoculation is plotted against virus dilution on a log-log scale (Fig. 1), a plateau value of 12-15% for dilutions  $5^{\circ}-5^{-3}$  is seen, followed by a decrease in percentage IF with increasing virus dilution. The slope of the curve is less than  $45^{\circ}$ .

When both lobes of the thymus were injected with 0.02 ml each of RadLV, virus-related antigens were detected as early as 2 d after inoculation of high concentrations of virus. The percentage of positive cells in all positive mice at one week was above 2%; among the negative mice, no positive cells were found among more than 20,000 examined. The endpoint titre for the  $5^{-9}$  virus dilution was detected by 7 d (endpoint titre  $1.9 \times 10^6$  per 0.04 ml). The curve obtained when the results were plotted on a log-log scale (Fig. 1) again has a slope much less than  $45^\circ$ , thus ruling out the interpretation, based on the results of unilobar injection, that the reduced slope might be due to selective virus-induced involution of the injected lobe 16. Instead, the slope of less than  $45^\circ$  is apparently due to secondary infection; accordingly, the assay yields valid results only as an endpoint dilution procedure.

In previous studies using the leukaemia induction bioassay<sup>6.7</sup>, it was shown that the intravenous (IV) route of viral injection is about 100 times less sensitive than the IT route. The same difference in sensitivity has now been observed with the new IF assay. At 3 week after IV injection of serial RadLV dilutions, the IF endpoint titre was  $3.1 \times 10^3$ , about 100 to 1,000 times less than that obtained after intrathymic injection.

Up to now the bioassay method<sup>6,7</sup> has been the only assay by which one could determine how many leukaemogenic particles were present in a given volume of RadLV preparation. To obtain a direct comparison of the two *in vivo* assays, the same stock of virus used for the unilobar IF assay described above was inoculated IT (0.02 ml) into one thymic lobe of C57BL mice. The endpoint was scored after 9 months

by determining the highest dilution of RadLV which induced lymphomas. The endpoint dilution was  $5^{-8}$  (titre  $3.9 \times 10^5$ ), in excellent agreement with the titre obtained after unilobar injection in the *in vivo* percentage IF assay. Several replicate *in vivo* IF assays, using IT injection, have indicated good reproducibility of the method.

The estimated titres obtained by three *in vitro* assay methods are as follows: the reverse XC cell test<sup>11</sup>, the percentage IF assay<sup>9</sup>, and the UCI-B focus assay<sup>5.13</sup> were comparable  $(1.9 \times 10^6 \text{ per } 0.4 \text{ ml})$  to those obtained with the new *in vivo* percentage IF assay.•The direct XC test<sup>3</sup>, however, and the indirect helper focus assay<sup>12</sup> gave lower  $(1 \times 10^5 \text{ per } 0.4 \text{ ml})$  and higher  $(9.6 \times 10^8 \text{ per } 0.4 \text{ ml})$  titres, respectively. *In vivo*-derived virus preparations have been more difficult to assay by rapid *in vitro* methods because major differences exist in viral growth kinetics between the *in vitro*-derived and *in vivo*-derived preparations of RadLV.

The new *in vivo* assay is direct, rapid, and sensitive. The highest dilution of RadLV capable of inducing a lymphoma is also the highest dilution capable of infection and active virus replication in thymus cells, as revealed by the appearance of virus-related antigens in the cell cytoplasm. The assay should therefore prove useful in elucidating the sequence of events *in vivo* between the time of virus inoculation and the ultimate development of lymphomas induced by this and other thymotropic MuLV.

### Sensitivity of cytotoxic T cells to T-cell mediated cytotoxicity

LYMPHOID cells sensitised against alloantigens can lyse in vitro target cells bearing these alloantigens1,2. In most of the experimental systems using in vivo sensitised cells, T cells (thymus-dependent lymphocytes) are both necessary3 and sufficient<sup>4,5</sup> for induction of target cell lysis. This seems to apply also to in vitro sensitised cells<sup>6-9</sup>. Specific cytolysis can be described as a two stage process: first, the recognition of target cell antigens by specific receptors at the surface of the 'killing' cell10,11; and, second, lysis itself.

Speculations about the mechanism of the second stage vary between two extreme hypotheses, that is, target cell lysis being exclusively due, either to direct membrane-membrane interaction with the killing cell, or to the effect of a nonspecific cytotoxic factor, a 'lymphotoxin', released in the surrounding fluid by the killing cell. Direct search for this or similar factors provided contradictory results<sup>12-23</sup>. To investigate the possibility of a lymphotoxin involvement, I resorted to a different approach.

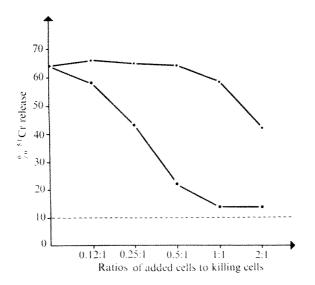

Fig. 1 Cytototoxicity, expressed as <sup>51</sup>Cr release, of mixtures of k anti-d killing cells and added cells. A constant amount of killing cells (2×106) was incubated overnight in the presence of various amounts of added cells, either normal d cells ( $\bullet$ ) or d anti-kcells ( ). The surviving cells were tested for their cytotoxicity against d target cells, as indicated in the legend of Table 1. -, Spontaneous release by target cells alone.

C3H anti-BALB/c (k anti-d) and BALB/c anti-C3H (d anti-k) sensitised cells were obtained after 5 d of coincubation at 37° C in a 10% CO<sub>2</sub> atmosphere of  $7\times10^6$  responding spleen cells and  $7\times10^6$  irradiated (2,000 rad) stimulating spleen cells in 2.5 ml of modified Factor and 10% had been spleen cells in 2.5 ml of modified Eagle medium plus 10% heat-inactivated foetal calf serum, in the presence of 10<sup>-6</sup> M mercaptoethanol<sup>27,28</sup>, per well of FB-16-24-TC Linbro plates.

\*Added cells were either normal BALB/c (d) spleen cells or Added cells were either normal BALB/c (a) specificells of sensitised d anti-k cells. They were transferred into type 2003 plastic Falcon tubes, in 1 ml of medium plus serum, with  $2 \times 10^5$  k anti-d sensitised killing cells, at the indicated ratios of added cells to killing cells. After one centrifugation at 180g for 5 min, the tubes were incubated overnight at 37°C and centrifuged again. The supernature were principled out 1 ml of fresh medium this serum was added as were pipetted out, 1 ml of fresh medium plus serum was added per tube and the resuspended cells were tested for their cytotoxicity and

counted in a trypan blue exclusion test

†Cytotoxicity was measured as follows. Target cells were P815 mastocytoma cells (d), labelled overnight with 100 μCi of <sup>53</sup>Cr in 1-2 ml as previously described<sup>s</sup>, washed twice and distributed in V-shaped wells of IS-MVC-96 Linbro microplates (10<sup>4</sup> P815 cells per 0.1 ml per well). Each well also received 0.1 ml of one of the cell suspensions tested for their cytotoxicity. The microplates were centrifuged (280g, 2 min) to increase the sensitivity of the cytotoxicity test<sup>5,29</sup>, incubated for 4 h at 37° C in a humidified CO<sub>2</sub> atmosphere and centrifuged again. Volumes of 0.1 ml of supernatants were sampled with an Eppendorf micropipette, their radioactivity was measured and expressed as % radioactivity initially present in 10<sup>4</sup> P815 target cells. Cytotoxicity, in this table, is expressed as % <sup>53</sup>Cr-release averaged from triplicate wells, minus 10% which was spontaneous <sup>51</sup>Cr-release his transfer of the second of t taneous  $^{51}$ Cr-release by target cells alone in each of these three experiments. The cytotoxicity for d target cells of d anti-k added cells alone was, for experiments one to three, 3, 3, and 2, respectively. This shows the degree of specificity of these anti-k cytotoxic cells. In this type of assay, an experimental difference of 5% or more is statistically significant  $(P=0.05)^{11}$ .

Percentage of trypan blue-excluding cells after overnight incubation, compared to the initial number of trypan blue-excluding cells in the mixtures of added cells and killing cells. These figures can be used to determine the experimental parameters not given in the table. For instance, for experiment three, column 0.5:1, the initial number of cells was  $10^6$  added normal cells plus  $2\times10^6$  killing cells, thus  $3 \times 10^6$  cells. The percentage of surviving cells was 27%, the number of surviving cells was thus  $8 \times 10^6$ . One tenth of this was used for the cytotoxicity test, giving a ratio to target cells of 8:1. The corresponding cytotoxicity was 60.

§Killing cells incubated alone, without added cells.

Let us provisionally make the hypothesis of a nonspecific cytotoxic factor, released into the extracellular fluid by the killing cell upon specific contact with the relevant target cell, which would be necessary and sufficient for subsequent target cell lysis. This extracellular cytotoxic factor would lyse the target cell, and should eventually lyse the cytotoxic cell as well. The cytotoxic cell is not lysed, however, either during or after the killing process 24,25, and is able to kill other target cells 2,3,28. The cytotoxic cell must then be resistant to the factor. If the cytotoxic cell (A) is subjected to the effect of other cytotoxic cells (anti-A), the anti-A cells would, by hypothesis, act against A cells through the release of a soluble factor. A cells, being resistant to the factor, must be resistant to the effect of anti-A cells as well. In other words, our initial hypothesis about a soluble factor leads to the prediction that cytotoxic cells should be resistant to other cytotoxic cells. In fact, I found that cytotoxic T cells are sensitive to the effect of other cytotoxic T cells specifically directed against them. This sensitivity, contrasting with the survival of the cytotoxic cell when it kills a target cell, argues strongly against an 'all lymphotoxin' mechanism accounting for the lytic event.

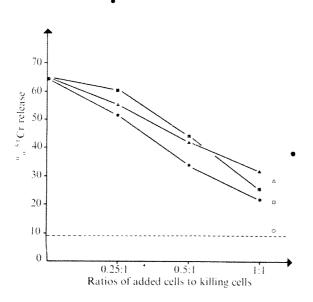

Fig. 2 Cytotoxicity, expressed as  ${}^{51}$ Cr release, of mixtures of  $b \times k$  anti-d killing cells and added cells. A constant amount of killing cells  $(2 \times 10^6)$  was incubated overnight in the presence of various amounts of added cells, either b anti-k ( $\blacksquare$ ), or k anti-b ( $\blacktriangle$ ), or d anti-k ( $\blacksquare$ ). The surviving cells were tested for their cytotoxicity against d target cells.  $\triangle$ ,  $\square$  and  $\bigcirc$  indicate cytotoxicity of added cells alone; ---, spontaneous release by target cells alone.

Experimental protocol similar to the one given in legend of Table 1, except that a constant amount of added cells ( $10^6$ ) is incubated overnight with varying amounts of killing cells. Killing cells were (C57BL/ $6 \times CBA$ ) F, hybrid anti-BALB/c cells. Added cells were either normal C57BL/6, or normal AKR, or C57BL/6 anti-C57BL/6 cells. For experiments one to four the spontaneous  $^{51}$ Cr-release by target cells alone was 9, 10, 12 and 8, respectively, and the cytotoxicity above spontaneous release of sensitised added cells alone was 5, 2, 10 and 8, respectively, which shows the degree of cross-reactivity of k anti-b cells in particular towards d target cells.

\*Added cells were not included. In these experimental groups the amounts of killing cells were the same as in the corresponding groups with added cells.

In a first set of experiments, C3H anti-BALB/c (H-2k anti H-2d; k anti-d for short) killing cells were incubated overnight together with either d anti-k or normal d 'added' cells. The residual anti-d cytotoxic activity of the mixtures in three consecutive experiments is given in Table 1. Cytotoxicity is much more depressed when d anti-k cells are added instead of normal d cells. An additional experiment showed (Fig. 1) that eight times more normal cells were necessary to depress cytotoxicity to the same extent as anti-k cells. The difference between both types of added cells was significant even at a ratio as low as 0.12 added cell to one killing cell, corresponding in this experiment to a final ratio of less than one added cell to one target cell. These results would be consistent with the possibility that the k anti-d killing cells are lysed or inactivated by the anti-k added cells, but other types of cell interactions, such as mechanical blocking30, booster or 'interkill' effects, may also be involved.

In a second set of experiments, I therefore used another strain combination. (C57BL/ $6 \times$  CBA)  $F_1$  hybrid anti-BALB/c killing cells ( $b \times k$  anti-d) were incubated overnight together with either d anti-k, or b anti-k, or k anti-b added cells. Use of the latter two types of added cells eliminates the possibility of blocking or interkill. A profound anti-cytotoxic cell effect of added cells was readily obtained in various experimental situations, for example when a constant amount of killing cells was preincubated with various amounts of added cells (Fig. 2), or when a constant amount of added cells was preincubated

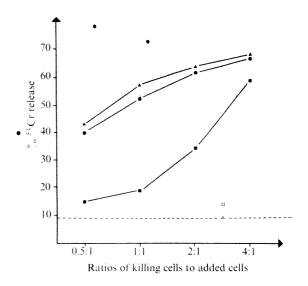

Fig. 3 Cytotoxicity, expressed as  ${}^{51}$ Cr release, of mixtures of  $b \times k$  anti-d killing cells and added cells. Various amounts of killing cells were incubated overnight either alone ( $\bullet$ ) or in the presence of a constant amount of added cells (10 ${}^{6}$ ). Added cells were either normal b cells ( $\bullet$ ) or b anti-k cells ( $\bullet$ ).  $\Box$  and  $\triangle$  indicate cytotoxicity of added cells alone.  $\frown$ , Spontaneous release of target cells alone. More complete data for this experiment are given in Table 2, experiment 1.

with various amounts of killing cells (Fig. 3 and Table 2). Clearly, incubation of  $b \times k$  anti-d killing cells with either k anti-b or b anti-k added cells led to a much lower residual anti-d cytotoxic efficiency than incubation with normal added cells. Finally experiments with anti- $\theta_{AKR}$  antiserum showed that the effect of k anti-b added cells on  $b \times k$  anti-d killing cells could be abolished by pretreatment of the added cells with anti- $\theta$  antiserum plus complement, but not with anti- $\theta$  antiserum or complement alone.

Addition to killing cells of cells specifically sensitised against them leads to a decrease of the cytotoxic efficiency of the killing cells. This is consistent with the possibility that cytotoxic

cells can be lysed by other cytotoxic cells. These cytotoxic cells may not be lysed, however, but merely functionally inactivated. Some degree of cell lysis definitely occurred in mixtures of killing cells and sensitised added cells, in which the number of surviving cells was usually lower than in mixtures of killing cells and normal added cells. In any case, even functional inactivation of killing cells without lysis, and a fortiori lysis itself, mean that killing cells are sensitive to the effect of other cytotoxic T cells directed against them.

This result is contrary to the prediction derived from my initial hypothesis of a lymphotoxin-mediated lysis. Complete rejection of this hypothesis, however, would be founded on the formal line of reasoning given above, which may be endangered by any parameter not included in its premises (for instance, resistance of cytotoxic cells limited to the short time when they actually kill, or existence of a different mechanism for lysis of tumour target cells and lymphoid cytotoxic cells). Still, the present report makes it much less likely that the lytic phase of specific T-cell mediated cytotoxicity is an 'all lymphotoxin' one, that is, one entirely accounted for by a nonspecific extracellular soluble factor. This does not exclude a role for soluble factors, which may still be involved, for instance if directly injected by the killing cell into the target cell, or as an extracellular agent completing membrane-induced lesions. Alternatively, no soluble factors at all may be involved, cytolysis being exclusively due to membrane-membrane interactions. Whatever the lytic mechanism turns out to be, because of killing cell sensitivity it would have to include a stage polarised towards the target cell.

I thank Miss Lynda Strong for technical assistance, and the Medical Research Council, the Imperial Cancer Research Fund and the Institut National de la Santé et de la Recherche Médicale for support. Anti- $\theta_{AKR}$  antiserum was given by P. Stern.

### Effects of cytotoxic sera on endothelium in vitro

THE rapid rejection of xenografts between widely different species, and the rapid 'hyperacute' rejection of vascularised allografts to previously sensitised recipients are both thought to be due to the effects of cytotoxic antibodies in recipient serum1.2. I have used cultured vascular endothelium to observe the direct effects of cytotoxic sera in vitro. Here I examine the effects on pig endothelium of dog serum (as a model for xenograft rejection) and of pig alloantisera to PLA antigens3 (as a model for hyperacute allograft re-

Endothelium was obtained from the aortae of five pigs of known PLA type by brief surface digestion with collagenase'. Shortly after death the aorta was cannulated by the left subclavian artery and flushed with cold saline. The vessel was dissected out from aontic arch to diaphragm, the intercostal arteries were ligated and a 4 F. G. Portex cannula was tied into each end. It was filled with a warm 0.2 w/v solution of Worthington collagenase (about 500 units ml-1) in tissue culture medium (TCM-Waymouths medium, Burroughs Wellcome, plus 10% heat inactivated foetal calf serum)—and incubated at 37° C for 15-20 min. Detached cells were flushed out with saline, washed with TCM, and plated out in glass 'medical flat' bottles. When required, the cells were resuspended with collagenase and plated at high cell density (150-200×10<sup>3</sup> ml<sup>-1</sup>) on to 13 mm diameter glass coverslips in plastic Bijou bottles containing 1 ml of medium. A confluent monolayer was usually obtained in 24 h (Fig. 1a). The coverslips were transferred to 30 mm plastic Petri dishes or to 'Sterilin' slide culture chambers for observation by inverted phase-contrast microscopy. Pigs were tissue typed on the basis of lymphocytotoxic assays using sera raised by skin grafting, kidney grafting or the injection of lymph node cells3. Baby rabbit serum was used as a complement source, after testing to exclude intrinsic cytotoxicity. Six different alloantisera were used to produce cytotoxic effects on the endothelial cultures. Experiments were done in duplicate; negative controls of pooled normal serum and compatible alloantisera were included. Fresh dog serum was obtained from three adult mongrels. Heat inactivated dog serum (56° C for 30 min) was used as a control. Pig and dog platelets were prepared from citrated blood by differential centrifugation. The platelet button was allowed to stand for 1 h at 37° C. washed in calcium-free TCM, and resuspended in TCM at a concentration of 500×106 ml<sup>-1</sup>.

Pig kidneys transplanted into dogs show a rapid decline in blood flow within a few minutes of vascularisation. The histological appearances are of almost total obliteration of the smaller vessels by thrombi containing platelets, fibrin and leukocytes. The time course can be slowed by perfusing the kidney with diluted or platelet depleted blood,

or with blood previously passed through a pig liver. Pig endothelium incubated with fresh dog serum showed changes within 15 min in each of four experiments with different endothelial lines, and the monolayer was completely disrupted within 90 min. The first change is that the endothelial cells become more rounded, and draw away from each other so that the cement lines after silver staining, which indicate close intercellular apposition, can no longer be demonstrated. The cells appear granular and vacuolated; many of them extrude cytoplasm as 'ghost bubbles'. At 90 min most of the cells have detached from the substrate and floated away. (Fig. 1b).

The damaged cells become 'sticky' to platelets-resuspended cells treated with dog serum and then mixed with

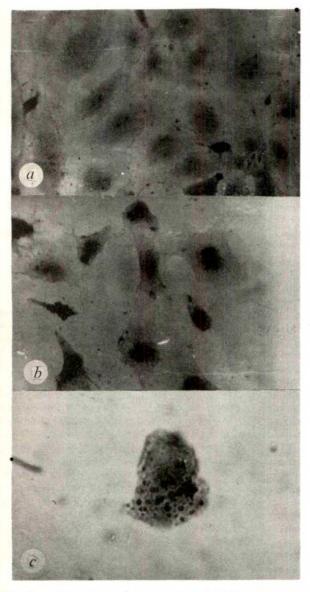

Fig. 1 a, Monolayer of normal pig endothelium in culture, stained silver and haematoxylin; b, pig endothelium treated for 30 min with 'lymphocytotoxic' antiserum, then for 35 min with baby rabbit serum; c, pig endothelial cell surrounded by platelets. About 75,000 resuspended endothelial cells were spun down and treated with 50  $\mu$ l of specific pig anti-PLA serum for 30 min, washed, treated with 100 µl rabbit serum for 30 min and added to 0.5 ml of pig platelet suspension. The mixture was gently shaken for 5 min in a siliconed tube. Smears were made and stained with Giemsa.

a dog platelet suspension become surrounded by platelets (Fig. 1c). Dog serum contains a heterophil antibody which agglutinates pig red cells and will cause their lysis in the presence of complement'. Adsorption of dog serum with pig red cells at 4° C renders it innocuous to pig endothelium, and pig endothelial cells incubated with heat inactivated dog serum will form cross agglutination rosettes with pig red cells.

Exactly comparable effects can be produced by incubating pig endothelium with 'lymphocytotoxic'-alloantisera and then treating it with rabbit serum as a complement source (pig serum is also effective, but some samples are 'anticomplementary'). In five experiments with different endothelial lines, changes were observed after 30 min and were marked at 60 min. Sera toxic to lymphocytes from a given pig were in each case toxic to endothelium from the same pig, but antisera to other specificities, pooled normal serum and specific antibody in the absence of complement were not. The damaged cells were again 'sticky' to pig platelets (these were obtained from pigs compatible with the antiserum used, to avoid the possibility of cross agglutination). The platelet-endothelial cell aggregates are similar to those described by Rafelson et al. after treatment of platelet-endothelial cell mixtures with thrombin6, and may be related to the platelet thrombi observed in vivo.

Similar effects on human endothelium have been observed as a result of treatment with antibodies to HL-A antigens (D. de B. and V. Joysey, in preparation).

I thank Professor R. Y. Calne, Mr M. Slapak, Dr V. Joysey and Mr D. White for help and advice; Mr D. White for providing tissue-typed pigs and pig antisera, and Mrs S. Rogers for providing dog blood. I am grateful to the Medical Research Council of Great Britain for a Junior Research Fellowship.

### Erratum

In the article "Thegosis in herbivorous dinosaurs" by R. A. Thulborn (Nature, 250, 729; 1974) the seventh line in para 4 should read 'facets usually occur towards the cervix at the anterior or' . . . and not as printed.

In the article "TRH potentiates behavioural changes following increased brain 5-hydroxytryptamine accumulation in rats" by A. R. Green and D. G. Grahame-Smith (Nature, 251, 524; 1974) Figs 1 and 2 were transposed over their appropriate legends.

In the article "B and T-cell stimulatory activities of multiple mitogens from pokeweed" by M. J. Waxdal and T. Y. Basham (Nature, 251, 163; 1974) Figs 2 and 3 have been interchanged. The legends are correct as they stand.

### Taxonomy of the Taung skull

discussing the implications of new age estimates for the South African australopithecine cave localities1, Tobias2 suggests if, on further study, it becomes necessary to transfer the Taung skull to the robust lineage, the morphological immaturity of this specimen would preclude its being designated the type specimen for the robust lineage. He further suggests that since this transfer removes the holotype from the paradigm of Australopithecus africanus, a lectotype needs to be designated for this species in accordance with Article 74 of the International Code of Zoological Nomenclature. Both of these suggestions are made without basis. The morphological maturity of a specimen or its relative completeness have no bearing on its validity as a holotype. The application of Article 74 is only appropriate when no holotype was designated for a nominal species in the original publication and syntypes exist from which a lectotype can be chosen. Since the Taung skull is still in existence and Dart<sup>3</sup> designated no syntypes, Article 74 cannot apply.

It can be appreciated that a renaming of the robust lineage, A. africanus, would create confusion for the students of human evolution; however, it is one of the greatest strengths of the Code that it is more difficult to change the validity of a name assigned to a type specimen than it is to change an interpretation based upon the type specimen. Interpretations may change with the seasons but the identity of a type is eternal. The principal purpose of the Code is to produce stability, uniformity and clarity in the way scientific names are applied. In so doing, it does not attempt to regulate the usage of names in reference to species lineages. The Code only concerns the relationship of species names to type specimens and establishes which nominal species have available names and how the type specimen of each is determined. It is the responsibility of the scientist to determine where the type fits in the zoological world and its evolutionary history. The rules of taxonomy and the resulting stability between type specimens and species names do not restrict one's freedom to rearrange specimens in whatever phyletic scheme is warranted by the evidence; it only regulates which names can be validly

applied to the scheme. Tobias's apparent contention that the transfer of the Taung skull to another lineage removes it from being the holotype of A. africanus is totally without basis. Transfer of a holotype from one paradigm to another does not affect the association of the holotype with its designated name. The species name remains with the holotype not with the associated paradigm.

A clearer picture of this taxonomic manoeuvring is seen if it is considered that the Taung skull is not being transferred but rather all other specimens previously associated with A. africanus are being removed from this paradigm and all specimens assigned to the robust lineage are being transferred to A. africanus. Should all the gracile specimens be removed from A. africanus the next available name for this group would be A. transvaalensis Broom, 1936, the holotype being the Sterkfontein TM 1511 skull'. This name has priority over A. prometheus Dart, 1948'; Telanthropus capensis Broom and Robinson, 1949°; and Homo habilis Leakey, Tobias and Napier, 19647.

This would indeed create a confusing state of affairs and it may seem that following the Code in this case would produce a condition contrary to its stated purpose. The Code (Article 79) does sanction the suppression of a valid species name under extremely exceptional circumstances where the purposes of stability and uniformity are better served by suspending application of the Code. This is the only available procedure for suppressing the usage of A. africanus in reference to its type specimen.

Recent years have witnessed a significant improvement in the condition of hominid nomenclature. Three factors have been most responsible for this improvement: first, palaeontologists have ceased regarding every new fossil hominid as a new species; second, palaeontologists, zoologists and physical anthropologists have expanded the concept of variability in palaeospecies making it possible to lump greater ranges of morphological variation within a single species; and, third, the International Code of Zoological Nomenclature has been closely followed by most workers. If hominid nomenclature is to continue to be as parsimonious as possible then a strict adherence to the International Code

of Zoological Nomenclature is mandatory.

PROFESSOR TOBIAS REPLIES-Olson has done palaeoanthropology a service in showing in what respects I misinterpreted the International Code Zoological Nomenclature, in the last three sentences of my article. Also, he has kindly and lucidly drawn attention to the intricacies of the correct nomenclatural procedures to be used. His comments on Taung are well taken, if one assumes the validity of (1) the original designation of A. africanus as the type-species of the new nominal genus Australopithecus (Articles 67-70 of the Code), and (2) the basing of the new nominal species on the Taung skull as its holotype (Articles 72-73).

If one assumes the procedures followed were valid, one is left with real problems which rigid adherence to the Code (except for Article 79) would in this instance bring in its wake, as Olson appreciates.

The crux may be stated as follows. The faunal evidence<sup>3,5</sup>, the estimated date of cave opening' and the sequence of geomorphological events, all point to a young age for Taung. If this age has been correctly inferred, it follows that either (1) Taung may represent a relict population of A. africanus; or (2) Taung does not represent A. africanus in the sense in which this taxon is understood from Makapansgat and Sterkfontein, a possibility suggested more than 5 years agos. (It does, of course, represent A. africanus, the original nominal species.)

If alternative (2) is correct, it would follow that Taung on the one hand, and Sterkfontein and Makapansgat on the other, may represent two different taxa.

In this event, I tentatively raised the possibility that the taxon represented by the Taung skull may be one of the robust taxa (for example, the super-

species, A. robustus/boisei). Indeed, fine morphological traits distinguish the Taung teeth from those of Sterkfontein and Makapansgat and, in a few instances, align them with those of the robust australopithecines7. If Taung proves to be robust, the confusing position set forth by Olson would follow. namely that the robust australopithecines would need to be added to the hypodigm of A. africanus, and the gracile australopithecines from Sterkfontein and Makapansgat would either remain as part of the hypodigm of a vastly more variable A. africanus, or need to be removed to form the hypodigm of another species (for which, as Olson points out, the nomen A. transvaalensis is available. Since there is now abundant evidence that the gracile and robust australopithecines are taxonomically distinct, the last-mentioned course would probably need to be adopted.

Such removal of the gracile australopithecines of Makapansgat and Sterkfontein from A. africanus would cause immense confusion, for the image of the species, A. africanus, is based largely on the hominids from these two sites, rather than on the skull of the Taung child, albeit the latter is the holotype.

No less of a muddle would ensue if palaeoanthropologists were now required to call the robust australopithecines A. africanus. It was to avert the resulting ambiguity that I raised the possibility of the holotype (the Taung skull) being removed from the paradigm of A. africanus—though I assumed and should have added, "if an appeal to the Commission under Article 79 of the Code were successful". In these unusual circumstances of extreme instability and confusion, not only is it reasonable to expect that such an appeal would be permissible under the Code (as Olson points out). but it might well be justified.

Meantime, the entire discussion has helped to establish the case for a comprehensive restudy of the Taung skull. Professor R. A. Dart, discoverer and nominator of the Taung skull, has generously invited me to undertake such a study.

### Paradox of Earth's core resolved

THE paradox of the Earth's core is hardly resolved by the recent comments of your Geomagnetism Correspondenti. Even your correspondent states that, because of uncertainties in the values of some of the physical parameters in the Earth's core, it is 'not possible to say whether convection in the core is feasible or not". He also states that "an origin (of the Earth's magnetic field), other than core convection, has never proved viable", and again "so sure are geomagneticians of the reality of core convection . . . It is certainly true that no completely satisfactory explanation has been given for the origin of the Earth's geomagnetic field. Most geophysicists, however, would support the idea that it arises from some kind of dynamo action in the core, but what drives the dynamo is very much a matter of contention. The two most reasonable proposals are thermal convection in the core and the Earth's precession; but in neither case has it been possible to establish that the mechanism would work.

Malkus<sup>2</sup> quoted experimental work and order of magnitude arguments to suggest that precession may produce turbulent motion in the core and thus drive the geodynamo. Such reasoning can, however, be seriously misleading, and contradictions can often result from over simplification. Malkus3 had earlier suggested that precessional torques may drive the geodynamo. Unfortunately, there are some errors in that article—the detailed theoretical investigation of a dynamo in a precessing turbulent core is extremely difficult and as yet no full treatment has been given. Rochester et al. (unpublished work) are working on this problem. At present it is impossible to reject precession as the driving mechanism for the geodynamo-it is as likely as thermal convection in the core.

Finally, your correspondent summarised the "flaw" in the Higgins-Kennedy argument that the core is stable against thermal convection'. That, however 'has already been pointed out (even more forcibly) by me' both in an earlier letter to Nature' and elsewhere6.

### Blocking one-way maternal-foetal MLR

THE findings of Jones and Curzen¹ both that lymphocytes from most mothers had low response to stimulating related cord blood lymphocytes in mixed leukocytes reaction, and that only autologous maternal plasmas but not homologous plasmas had an inhibitory effect among those that had relatively high responses, are interesting. Despite the fact that the mixed lymphocyte reaction as measured after 6 d of incubation reflects the sensitisation and responsiveness in vitro rather than the state of previous sensitisation in vivo as demonstrated by us with the macrophage migration inhibition technique<sup>2-4</sup>, the results are consistent with our previous report3. It seems that the plasma blocking factors can also inhibit specific sensitisation in vitro of maternal cells as well as prevent the expression in vitro of cell mediated immune reactivities of lymphocytes previously sensitised (in vivo) to solubilised placental antigens as reported.

On the other hand, the findings of low maternal lymphocyte response to related foetal cells does not warrant the conclusion that maternal lymphocytes may somehow be affected by previous exposure to the plasma blocking factors. The results could as well be accounted for by the abnormality of the foetal cells in their effectiveness as stimulating cells. In fact, if previous exposure had any effect at all, the surface antigens of the foetal cells are a more likely target. The intact responsiveness of the maternal lymphocyte to stimulating related cord or unrelated adult lymphocytes in oneway mixed lymphocyte reaction was indicated by studies by Carr et al.3.

### APPOINTMENTS VACANT

### ACADEMIC POSITION

One immediate opening for a Ph.D. chemist, preferably in the area of analytical chemistry with research interest in biomedical applications. Duties include graduate and undergraduate teaching and establishing a vigorous research programme. Rank open. This position has been created through a grant from the Minority Schools Biomedical Support Programme of the National Institutes of Health. Successful applicants will be required to interact strongly with minority students in this programme. Send résume to: Dr Ralph G. Wilkins, Head, Department of Chemistry, Box 3C, New Mexico State University, Las Cruces, New Mexico 88003. New Mexico State University is an equal opportunity and affirmative action employer. (1489) (1489)

### POSTDOCTORAL RESEARCH

POSTDOCTURAL RESEARCH

Mass Spectrometry ion source research on ionisation of non-volatile organic and biochemical compounds from a liquid surface. Research includes instrumentation, parametric studies and applications development. Related experience in mass spectrometry, analytical instrumentation, AEI MS-9, mini-computers, and/or MS of organic or biochemical compounds considered important. Salary \$11,000 to \$11,500. Two-year appointment possible. Contact C. A. Evans, Ir., Materials Research Laboratory. University of Illinois, Urbana, Illinois 61801 U.S.A. (1521)

### ASSISTANT PROFESSOR IN **PALEONTOLOGY** UNIVERSITY OF TORONTO

Ph.D. required from July 1, 1975, with teaching and research interests in invertebrate paleontology or micro-paleontology and its stratigraphic applications. Duties include undergraduate and graduate teaching, development and maintenance of a research programme, and supervision of graduate students. Salary dependent on qualifications and experience. Address enquiries to Dr D. W. Strangway, Chairman, Dept of Geology, University of Toronto, Toronto, Ontario M5S 1A1, Canada. (1591)

### POSITION OPEN ASSISTANT PROFESSOR

Applications are invited from qualified persons holding Ph.D. and/or M.D. degrees to fill a new position, preferably at the Assistant Professor level, in GROSS AND MICROSCOPIC ANATOMY, in the School of Basic Medical Sciences, Urbana-Champaign. Appropriate departmental predoctoral or postdoctoral training is essential.

cssential.

The position will carry a joint appointment in one of the scientific departments on this campus. Teaching duties relate to curriculum development and supervision of medical student learning in an independent study programme. Candidates must have demonstrated their capacity for original research as evidenced by publications of high quality.

research as evidenced by publications of high quality.

The University of Illinois is an Affirmative Action—Equal Opportunity Employer and encourages applications from members of minority groups and women.

Send application, including curriculum vitae, publication list, important reprints, and at least three letters of recommendation to Dr Ray L. Watterson, Chairman, Search Committee.

Morrill Hall, University of Illinois, Urbena, Illinois 61801.

# Research Fellowships

at Continental Universities

Applications are invited for awards by the CIBA-GEIGY Fellowship Trust for the academic year 1975-76.

Two classes of award will be made as follows:

CIBA-GEIGY Fellowships
CIBA-GEIGY Fellowships are offered to graduates of universities of the United Kingdom and the Republic of Ireland for research into chemistry, biochemistry, chemical technology including chemical engineering, and biology, particularly in its relation to chemistry, at an agreed university including a technological university on the continent of Europe.

Qualifications recent first degree university graduates normally resident in the UK who intend to undergo training is research for a doctorate or other higher degree at an agreed European university including a European technological university.

Duration of the award the minimum required by the university regulations subject to satisfactory progress,

with the possibility of an extension for an additional year.

Scale of awards £1,900 per annum (£2,200 per annum if married) plus travelling expenses.

The candidate should not be in receipt of any other award.

Senior CIBA-GEIGY Fellowships

Senior CIBA-GEIGY Fellowships are offered to lecturers, senior lecturers, readers or those holding comparable positions at United Kingdom or Republic of Ireland universities who are also graduates of these universities and wish to undertake special study at an agreed continental European university including a European technological university.

Duration of the award minimum period of six months and up to two years

Scale of awards £5,000 per annum plus travelling expenses.

Further details and application forms, which should be submitted before 31 January 1975, can be obtained from The Secretary, The CIBA-GEIGY Fellowship Trust,

30 Buckingham Gate, London SW1E6LH.

(1653)

UNIVERSITY HOSPITAL OF WALES, HEATH PARK, CARDIFF.

CYTOGENETICS UNIT, DEPARTMENT OF CHILD HEALTH.

# ASSISTANT **CYTOGENETICIST**

Applicants are invited from Graduates in one of the biological sciences preferably with an Honours degree, for the above new post in the Regional Cytogenetics Unit which already has a graduate staff of five. Previous experience in tissue culture or cytogenetics is desirable but not essential.

Starting date as soon as possible after 1st December, 1974.

Salary—within the range of £2,046 per annum to £2,994 per annum. Starting salary dependent on qualifications and experience.

Terms and conditions of service in accordance with Whitley Council regulations.

Application forms and further particulars from the Personnel Department, University Hospital of Wales, Heath Park, Cardiff. Closing date: November 15, 1974. (1662)

# Scientists & Engineers

# Help to ensure Safety and Health in the Industrial Environment.

The advancement and diversification of industrial technology has increased potential health and safety hazards. Helping to eliminate or control these hazards could be your role with the Factory Inspectorate (shortly to be part of the new Health and Safety Commission which is being set up to deal with all aspects of safety and health at work).

Current opportunities are based in the Inspectorate's Industrial Hygiene Laboratories at Cricklewood, London, which are superbly equipped and rival the best in the world. However, you will have the opportunity to be out and about, visiting factories and sites etc. and you will need to be able to communicate effectively with both management and the workforce.

The vacancies are in the following areas:

### Air Flow Analysis

Supervise group investigating flow patterns of air bearing dust and fumes in exhaust ventilation plant and calibrating and effecting minor repairs to air flow and chemical environment measuring instruments. Develop and study methods. Higher Scientific Officer. Ref: SB/8/DB. Analysis of Dust and Fumes

Supervise small group analysing atmospheric samples from factories. Investigate sampling/analysis methods. Requires competence in both classical and instrumental methods of analysis. Higher Scientific Officer. Ref: SB/9/DB. Radiological Survey

Carry out surveys at factories, using portable electronic equipment and air samplers. Conduct laboratory examination of samples, and calibrate and maintain monitoring equipment. Requires basic knowledge of electronics and physics.

Experience in health physics, liquid scintillation counting or electronic equipment maintenance desirable. Scientific Officer. Ref: SB/10/DB.

### **Analysis of Toxic Materials**

Laboratory analysis of samples from factories. Some travelling with Factory Inspectors for sampling and on-the-spot analysis. Knowledge of instrumental analytical techniques an advantage. Scientific Officer. Ref: SB/11/DB.

### Testing of Dusts and Inflammable Liquids

Provide technical and scientific support for accident and explosion investigations. Frequent travel. Requires experience in metallurgy, chemical analysis or development of pilot testing methods using instrumental techniques. Mechanical/electrical engineering knowledge an advantage. This section will be moving to Buxton, Derbyshire, probably early in 1975, but there will be ample opportunity for staff to remain in London. Several posts for Scientific Officers. Ref: SB/12/DB.

Candidates must hold a degree/HNC/HND in an appropriate scientific or engineering subject. The ability to drive a car would be an advantage. For appointment as Higher Scientific Officer (£2850 – over £3750) they should normally be under 30, and have at least 5 years' postgraduate experience. For a Scientific Officer appointment (around £2000 – over £3050) they should normally be under 27.

For full details and application form (to be returned by 22 November 1974) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB or telephone BASINGSTOKE 29222 ext. 500 (or, for 24 hour answering service, LONDON 01-839 1992).

Please quote appropriate reference.

### M.R.C. CLINICAL RESEARCH CENTRE

(Northwick Park Hospital) WATFORD ROAD, HARROW, MIDDLESEX HAI 3UJ

### **TECHNICIAN**

with H.N.C. or ordinary degree and preferably tissue culture experience to work on a project in the Division of Cell Pathology and Section of Histopathology involving the transplantation of human tumours.

Salary within the scale £1,860 to £2,835 plus £126 London Weighting and threshold increase.

Please write to Mrs J. Tucker-Bull for application form and further details. Ref. 130/2/3978.

### (1586

# UNIVERSITY OF NEWCASTLE-UPON-TYNE

DEPARTMENT OF CHEMICAL ENGINEERING

Applications are invited from suitably qualified persons for appointment as

### RESEARCH OFFICER

until July 31, 1977. Candidates should have a good knowledge of the physics of diffusional processes and be interested in joining a team studying mass transfer phenomena in liquid-liquid systems. The person appointed will also be expected to undertake limited teaching duties.

The salary will be in the range £2,118 by £129 to £2,247 by £165 to £2,412 according to age, qualications and experience with F.S.S.U. benefits.

Applications should reach Professor J. D. Thornton, Department of Chemical Engineering, University of Newcastle-upon-Tyne, not later than November 16, 1974. (1701)

### LEICESTER MUSEUMS, ART GALLERIES AND RECORDS SERVICE TEACHER-LEADER-NATURAL SCIENCES

Salary AP 3/4 £2,187 to £2,880 (plus threshold)

We need an experienced and enthusiastic natural sciences teacher with keen interest in fieldwork and wide general interests in Natural History to work in an educational team with History and Art Specialists in a new approach to museum interpretation. Working in close co-operation with curatorial staff, the teacher leaders will be responsible for advising educationalists on the realisation of the full potential of the museum's resources.

The post will also be involved with children's activities and lecturing and teaching at all levels. Opportunity will be given for personel research in areas relevant to the post.

Further details, job description and application form can be obtained from Patrick J. Boylan, Director of Museums, Art Galleries and Records Service, New Walk, Leicester LE1 6TD. (Tel. Leicester (0533) 539111 Ext. 261).

Closing date for completed application forms November 10, 1974. (1660)

### Agricultural Research Council

### POULTRY RESEARCH CENTRE

Applications are invited for a post within the Scientific/Higher Scientific Officer grades in the Ethology Section of the Poultry Research Centre, for work on reproductive behaviour. The project involves a certain amount of surgery and neuro-anatomy. The person appointed should be prepared to supervise Technical staff.

Candidates should have a pass degree or H.N.C. in an appropriate biological subject but specialisation in Ethology is not a necessity.

Salary within the scales £1,592 to £2,675 or £2,461 to £3,371 per annum with placement according to qualifications and experience. In addition, threshold cost of living increases are payable. A minimum of five years post qualifying experience is required for appointment in the higher grade. The post is pensionable under a non-contributory superannuation scheme.

Application forms, which may be obtained from the Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3JS, should be completed and returned to him not later than November 20, 1974. (1628)

### UNIVERSITY OF LEICESTER

### CHAIR OF BIOCHEMISTRY

The University invites applications for the CHAIR OF BIOCHEMISTRY, to become vacant at October 1, 1975, following the appointment of Professor H. Kornberg, F.R.S. to the Sir William Dunn Professorship of Biochemistry at the University of Cambridge. The holder of the Chair will also be HEAD OF THE DEPARTMENT for a period to be arranged. The salary will be within the professorial range.

Further particulars from the Registrar, to whom applications should be sent by December 18, 1974. (1650)

### BOTSWANA

# **EUTOMOLOGIST**

Required by the Department of Agriculture to conduct investigations into the distribution and ecology of the tsetse fly, to evaluate insecticides and control techniques, and to train staff.

Candidates should have an Honours Degree in a biological science, preferably Eutomology or Zoology, with recognised post-qualification experience.

Salary will be in the scale of £2,660 to £5,400 p.a., which includes an allowance, normally tax-free, of £480 to £1,560 p.a. This allowance is currently under revision.

Benefits include 25% gratuity of basic salary, paid passages, generous leave, children's holiday visit passages, education allowances, and accommodation at reasonable rental. A car loan up to £600 and an appointment grant up to £300 may also be payable. Initial tour 2—3 years.

The post described is partly financed by Britain's programme of the developing countries administered by the Ministry of Overseas Development. For further particulars you should apply, giving brief details of experience to:

# crown agents

M Division, 4 Millbank, London SWIP 3JD, quoting reference number MID/740608/NF. (1657)

# **Microbiologist**

An opportunity exists for a microbiologist to join a project involved in the field of novel antibiotics research.

This interesting and challenging post requires a person with wide microbiological interests. Previous experience in antibiotic: research would be an advantage, though a recently qualified person would be considered.

A good starting salary will be offered and reviewed regularly. Beecham Pharmaceuticals, Research Division is part of the Beecham Group and is situated in a pleasant area of Surrey, within easy reach of London.

The successful applicant will qualify for the Group's generous bonus scheme and non-contributory pension and life assurance scheme.

If you are interested in this vacancy please contact the Site Personnel Officer, Beecham Pharmaceuticals, Research Division, Brockham Park, Betchworth, Surrey, RH3 7AJ, or ring Betchworth 3202 ext. 55 for an application form.

THE QUEENS AWARD TO INDUSTRY 1966 1970 1971 1972

# HAXO

### **Nutritional Adviser**

GLAXO-FARLEY FOODS, the foods division of Glaxo Laboratories Limited, requires a Company Nutritionist reporting to the Divisional Marketing Manager.

The position is located at the Plymouth Divisional headquarters and involves advising the Division generally on all nutritional ematters especially infant nutrition. This will include screening copy for sales packs and sales literature. He or she will help in the identification and composition of new products and will be responsible for arranging clinical trials of products and for maintaining appropriate professional contacts. Preparation of review articles, clinical papers and some lectures on nutrition will be necessary.

The position will involve some travel in the U.K. and will be both interesting and stimulating in a marketing orientated environment.

Applicants should be suitably qualified Nutritionists and/or dietitians with some previous experience.

We offer a competitive salary and excellent conditions of employment including bonus and pension schemes, and four weeks' holiday.

Please write for an application form, quoting ref. U 902 to the Personnel Officer (JSP), Glaxo Laboratories Limited, Greenford, Middlesex.

Scientific **Information Assistant** 

A young graduate in a biological science is required to join a team working on the organization of scientific information and new product registration in a research-based pharmaceutical company. The successful candidate will have an aptitude for the organization of scientific data, a wide interest in scientific and medical topics and will be able to write clear concise English. The vacancy provides a valuable introduction to information work for a graduate who does not wish to specialize.

Please apply to:

Mr C. E. Henry Staff Personnel Manager, John Wyeth & Brother Limited, Huntercombe Lane South, Taplow, Nr. Maidenhead, Berks. or Telephone: Slough 28311.

(1677)

### THE LONDON HOSPITAL

(WHITECHAPEL)

### MEDICAL PHYSICS TECHNICIAN

Applications are invited for the above post in the Heart Lung, Intensive Therapy Unit and Anaesthetic Research Unit of The London Hospital. The post will be both technical and scientific and will involve clinical measurement, blood gas analysis, gas analysis and the operation of Heart Lung equipment, i.e. pump, transducers, monitoring equipment and hyperthermia equipment.

Preference will be given to graduates in Biology and Physics but applicants with relevant 'A' levels in Biology or Physics may also apply. Opportunities will be available for further study.

Minimum starting salary will be £1,899 (increase pending) threshold payments.

For application forms, please ring or write to Moira Payne, Administrator Personnel Services, The London Hospital (Whitechapel), London E1 1BB, Tel. 01-247 5454 Ext. 388. (1649)

### CHELSEA COLLEGE University of London **ENVIRONMENTAL** MONITORING PROJECT

Applications are invited for the following research Applications are invited for the following research posts associated with a three year study, sponsored by the Department of the Environment, on the collection, collation, manipulation and assessment of data which will flow from existing and planned monitoring activities at national, regional and global levels:

global levels:

ONE ENVIRONMENTAL SCIENTIST
(Salary range £2,580 to £5,976)\*

ONE SYSTEMS ANALYST
(Salary range £2,580 to £5,976)\*

ONE RESEARCH ASSISTANT IN
ENVIRONMENTAL SCIENCE
(Salary range £1,809 to £2,580)\*

ONE RESEARCH ASSISTANT IN
SYSTEMS ANALYSIS
(Salary range £1,809 to £2,580)\*

\* In addition a London Allowance of £213 per annum and Threshold Payments will be made.
Where appropriate Secondment may be arranged.
The programme is designed to:
(a) Review the current status of environmental

(a) Review the current status of environmental problems and monitoring practices.
 (b) Define needs and goals in the near future.

(c) Determine the most efficient procedures for realising these objectives.

The team will be directed by Professor G. T. Goodman, Chelsea College, Application forms and further particulars from the Personnel Officer, Chelsea College (N), Manresa Road, London SW3 6LX. Closing date for receipt of applications November 14, 1974. (1700)

### UNIVERSITY COLLEGE DUBLIN APPOINTMENT IN CHEMISTRY

APPOINTMENT IN CHEMISTRY

Applications are invited for a teaching post in the Department of Chemistry, Candidates should have a special interest in Physical Chemistry.

The current salary scales are:
College Lecturer: £3,514 by 162 to £4,648
Assistant Lecturer: £2,420 by 129 to £3,323
Entry point on the relevant scale will be in accordance with qualifications and experience.
A non-contributory pension scheme and family allowances are additional to salary. An alternative contributory F.S.S.U. type pension scheme is also available.

Prior to application, further information (including application procedure) should be obtained

avanable.

Prior to application, further information (including application procedure) should be obtained

Mr. J. P. MacHale, Secretary and Bur University College, Belfield, Dublin 4.

Telephone 693244 Extn. 431.
Latest date for receipt of completed applications riday November 22, 1974. (1656)

### **BIOCHEMIST**

Ph.D. or equivalent. Must have laboratory experience in vitamin D chemistry or action. To establish a vitamin D-focused laboratory programme in cona vitamin D-focused laboratory programme in conjunction with university calcium researchers. Position at Research Institute. The Hospital for Sick
Children, Toronto, with faculty appointment in
Department of Biochemistry, University of Toronto.
Salary commensurate with experience and qualifications. Apply before December 1st enclosing
curriculum vitae and names of two referees, to:—
The Secretary, Research Institute, The Hospital for
Sick Children, 555 University Avenue, Toronto,
Ontario, M5G 1X8, Canado. (1661)

### ASSISTANT PROFESSOR WILDLIFE BIOLOGY

Position available as a joint appointment in Institute of Animal Resource Ecology and Department of Zoology beginning in July 1975 for one person to develop an integrated program in wildlife studies and resource management. Candidate must have ability to do quantitative field studies on larger mammals or birds and to direct graduate work on wildlife species. Teaching will involve one undergraduate course in ecology or behaviour and a graduate course in area of specialization.

Curriculum vitae and names of three referees should be sent to Dr. W. G. Wellington, Director, Institute of Animal Resource Ecology, University of British Columbia, Vancouver, Canada V6T 1W5. Closing date: January 31, 1975. (1665)

### **BIOCHEMICAL JOURNAL EDITORIAL ASSISTANT**

required. Duties consist mainly in preparing papers for the printer and proof-reading for the Biochemical Journal and other Biochemical Society publications. A good degree in biochemistry or related subject is essential. Some postgraduate related subject is essential. Some postgraduate experience in laboratory and/or editorial work is desirable, though not essential. The commencing salary will be in the incremental range £2,331 to £2,625 per annum. Please apply in writing, giving the names of two referees, to the Editorial Secretary, Biochemical Journal, 7 Warwick Court, London WCIR 5DP. (1691)

# CHEMIST or BIOCHEMIST

Graduate chemist or biochemist to study the metabolism of foreign compounds. Several years of relevant experience is essential.

# MICROBIOLOGIST

Graduate microbiologist to join a small team using organ and tissue culture in toxicology and carcinogenesis studies.

# ANALYTICAL CHEMIST

To develop methods for the analysis of drugs in biological fluids.

Competitive salaries, non-contributory pensions and free life assurance are offered by this rapidly-expanding contract research company. situated in beautiful rural surroundings, 40 minutes from London.

Please send your curriculum vitae to: J. W. Daniel, D.Sc., Director of Metabolic Studies.

LIFE SCIENCE RESEARCH Stock, Essex CM4 9PE

(1692)

# nature

A vacancy will arise soon in the Washington office of *Nature* for the important post of Assistant Editor responsible for supervising the refereeing of biological manuscripts submitted to the Washington office. A period of training in the London office under the supervision of the Biological Manuscripts Editor will precede the posting to Washington. The successful applicant may expect to be in Washington for not less than two years.

This job is an outstanding opportunity for a recently qualified British or American Ph.D who has a strong interest in ensuring the high quality of the biological papers we publish.

Apply with curriculum vitae and the names of two referees to:—

The Editor. Nature, Macmillan Journals Ltd., 4 Little Essex Street. London, WC2R 3LF

by November 15th

### **British Museum (Natural History)**

Study the variations exhibited by molluscan faunas of freshwater habitats 
Undertake curatorial and advisory work on land and freshwater molluscs.

☐ Degree, preferably 1st/2nd hons or equivalent in Zoology ☐ Keen interest in evolutionary biology and taxonomy ☐ Experience of techniques for examining biochemical variation an advantage ☐ Age under 27 ☐ Appointment as

Scientific Officer (over £2150 to around £3250) 

Ref: SB/36/DK.

Application forms (for return by 22 November 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 (or, for 24 hour answering service, London 01-839 1992).

> **Ministry of Overseas Development** Tropical Products Institute, Slough

# **Crop Storage Engineers**

R & D and advisory work on structures and systems for handling and storage of cereal grains and other crops in developing countries ■ Assist in training of storage technologists from overseas ■ Overseas assignments may be required.

Degree or equivalent in Agricultural, Mechanical or Civil Engineering Knowledge of simple structural design grain storage systems desirable ☐ Experience in tropical or sub-tropical countries an advantage ☐ Age under 30 ☐ Appointment as Scientific Officer (around £1750 – over £2800) or Higher Scientific Officer (£2600 - over £3500), according to age and experience Ref: SA/35/JD.

☐ Application forms (for return by 15 November 1974), from Miss C A Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.

Ministry of Agriculture, Fisheries and Food Food Science Division, Norwich

■ (Ref: SB/13/AE) To lead team investigating reactions of nitrite with food components 
Study rates and products of C-, S- and N-nitrosations in meat 
Relate results to nitrite losses during meat processing, distribution and culinary preparation Develop analytical methods for measuring nitrite products.

☐ 1st/2nd hons degree in Chemistry or related subject ☐ At least 2 years' relevant postgraduate experience, preferably including analysis of trace compounds in complex media  $\square$  A working knowledge of reaction kinetics in biological systems an advantage  $\square$  Age under 30  $\square$  Appointment as Higher

Scientific Officer (£2600 – over £3500).

(Ref: SB/14/AE) In team investigating reactions of nitrites in meat 
Study S-nitroso compounds as nitrosating agents and as a nitrite 'sink' 
Reflected findings to nitrite loss in meat and compounds present in food eaten.

☐ Ist/2nd hons degree in Chemistry or related subject ☐ Interest in analytical and kinetic aspects of organic chemistry in systems of biological origin desirable  $\square$  Age under 27  $\square$  Appointment as Scientific Officer (around £1750 –

Application forms (for return by 19 November 1974), from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 (or, for 24 hour answering service London

(1724)

### UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY

Research Officer required to work in radio-immunoassay in relation to disease in man. Pre-vious experience desirable but not essential. Salary in the region £1,593 to £2,229, plus Threshold pay-ments, depending on experience.

Write giving curriculum vitae to Professor Vin-cent Marks, Department of Biochemistry, University of Surrey, Guildford, Surrey GU2 5XH. (1658)

### ROYAL HOLLOWAY COLLEGE, (UNIVERSITY OF LONDON),

Egham Hill, Egham, Surrey.

Applications are invited for a Research Assistant to work on enzyme studies in tropical fruit. Candidates should have a good Honours degree in Biochemistry or Chemistry. There is the possibility of registering for a higher degree of the University of London.

Please apply to Professor J. B. Pridham, Department of Biochemistry. (1668)

### MOLECULAR BIOLOGIST

MOLECULAR BIOLOGIST
The National Institute of Environmental Health Sciences invites applications for a Molecular Biologist position under the Staff Fellow or Visiting Associate Programme. As a member of a multidisciplinary group studying developmental toxicology, the selected applicant will plan and conduct independent and collaborative research in the area of the molecular basis for chemically-induced alterations in developing systems.

A doctorate in Biochemistry or a related disippline is required.

The appointment will initially be for one or two years and may be extended. Salary will range from \$15,000 to \$20,000 per annum depending on qualifications.

Letters of application with curriculum vitae, bibliography and name and address of two references should be addressed to:

Mr Charles E. Walker

National Institute of Environmental

Health Sciences

P.O. Box 12233

Research Triangle Park,

North Carolina 27709

Letters must be received by December 10, 1974 to be considered.

An Equal Opportunity Employer (1715)

to be considered. An Equal Opportunity Employer (1715)

### MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH

### DIVISION OF VIROLOGY

Applications are invited from young postdoctoral virologists for a position within a group concerned with basic mechanisms of virus infection using the adenovirus model system. This post should be of interest to those who have experience of any branch of molecular biology. The appointment will be for up to three years and will be in the salary range £2.412 to £3.636 p.a. according to age and qualifications (plus London and threshold allowances). Superannuation provision under F.S.S.U. Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director. National Institute for Medical Research, Mill Hill, London NW7 1AA before December 6, 1974. (1666)

### UCLA

UCLA

University of California, Los Angeles, Department of Geology invites applications for two-year faculty appointments as assistant professor. A Ph.D. is required. Two faculty two-year positions will be available beginning September 1975. Applicants must have truly superior capabilities in one or more of the relevant basic physical or biological sciences. Two earth scientists will be selected from the three following general areas:

(1) Those engaged in research in one or more of the fields (a) igneous or metamorphic petrology; (b) ore genesis: (c) experimental or theoretical geochemistry; (d) mineral physics. Examples of emphasis include thermodynamics of irreversible processes and chemical or thermal diffusion.

(2) Those engaged in research in the areas of tectonophysics, geological physics, or structural geology. Of particular interest are: (a) solid-state aspects of microscopic phenomena-fracture and flow of rocks, diffusion, thermodynamics, and lattice dynamics; (b) global tectonics; (c) quantitative modelling of large or small scale processes.

(3) Marine science, those engaged in research in organic geochemistry, ecology, or marine geology. Examples of emphasis include diagenesis of sediments, interstitial water, evolution, phycology (calcarcous algae), invertebrate biology, and global tectonics.

Send vitae and two letters of reference to:

(cafeareous aigae), invertebrate 0000/gs, and global tectonics.

Send vitae and two letters of reference to:
Clarence A, Hall, Chairman
Department of Geology
University of California Los Angeles
Los Angeles, California 90024

Minority and ethnic earth scientists are encouraged to apply. UCLA is an affirmative-action/equal opportunity employer. (1654)

### **ELECTRON MICROSCOPY** TECHNICIAN

required with experience in Electron Microscopy to collaborate on a project involving study of Tumour Virus DNA.

Salary according to qualifications and experience. Write or telephone for application form to Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, W.C.2. on 242 0200 ext. 305. (1716)

### KENNEDY INSTITUTE OF RHEUMATOLOGY CHIEF TECHNICIAN

required for the Division of Experimental Pathology. The work involved is mainly of a research nature and histology autoradiography, and electron microscopy services are provided for other divisions in the Institute.

sions in the Institute.

This is a well equipped, modern laboratory investigating lymphoid tissue function. All the usual techniques required to study cells and tissues are employed. A suitable candidate would be expected to have the relevant background experience as well as to be prepared to take on administrative responsibilities. Written applications giving full curriculum vitae and naming two referees to: Laboratory Superintendent, Kennedy Institute of Rheumatology, Bute Gardens, London W6 7DW.

(1507)

(1507)

### INFORMATION SCIENTIST

Borax Consolidated Limited, an International company within the R.T.Z. Group, requires an Information Scientist for the Information Department at its Research Centre in Chessington, Surrey. The information team is responsible for providing the Borax companies throughout the world with technical, patents, and commercial information.

technical, patents, and commercial information. Candidates should have a degree (or equivalent qualification) in chemistry or a related field Previous experience in information work is desirable and fluent reading ability in one of more modern languages will be a distinct advantage. Every opportunity will be given to the successful candidate for fullest utilisation of ability and initiative. The post offers an attractive starting salary and excellent fringe benefits, including a non-contributory pension scheme.

Please apply for an application form to: The

Please apply for an application form to:—The Personnel Manager, Borax Consolidated Limited, Borax House, Carlisle Place, London SWIP 1HT. Tel: 01-834 9070. (1659)

### WEST BERKSHIRE HEALTH DISTRICT MEDICAL PHYSICS TECHNICIAN

for the modern Isotope Laboratory at the Royal Berkshire Hospital, Reading for interesting work in the chemistry and physics of medical isotope techniques. Post will be on Grade IV £1,773 to £2,463 plus additional threshold payments. Day release for further training possible. (Normally ONC or 2 'A' levels required).

Reading is a pleasant University town offering easy access to London, Oxford, Windsor, Henley and attractive Thames country-

written applications with details and naming 2 referees to: Hospital Secretary, Royal Berkshire Hospital, London Road, Reading, Berkshire. (1720)

### GRADUATE RESEARCH ASSISTANT

required in the Department of Nuclear Medicine for work involving the quantitation of radioisotope images using two Gamma cameras interfaced with a mini computer. Mathematics and experience in computer programming essential.

Salary in range £1,758 to £2,022.

Applications to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. N.M., enclosing a curriculum vitae and the names of two referees.

### SURREY EDUCATION COMMITTEE EWELL COUNTY TECHNICAL COLLEGE

Reigate Road, Ewell, Surrey Principal: B. Haynes BSc DipEd FRIC DEPARTMENT OF BIOLOGICAL SCIENCES

Require as soon as possible:

LECTURER I to teach Cell Biology and/or Biochemistry for H.N.C. in Medical Laboratory Subjects. The College is an approved centre for this course. Some experience of Medical Microbiology or Histopathology and an interest in research on problems of learning in the bio-medical field would be advantageous.

Applicants with suitable experience will have the opportunity to teach MIBiol (Hons, BSc.) level. Salary: £1,800 to £2,874 p.a. For Gd Hons, Grad, the scale is extended to £3,045 p.a. £141 p.a. London Allowance payable, (Subject

to confirmation)

Generous relocation expenses and assistance with house purchase in approved cases.

Stamped addressed foolscap envelope please for further particulars and application form from the Vice-Principal. Applications to be returned within 14 days. (1674)

# CSIRO

### **AUSTRALIA**

# DIVISION OF TROPICAL **AGRONOMY**

# KIMBERLEY RESEARCH STATION KUNUNURRA, W.A.

# RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists-located in Divisions and Sections throughout Australia.

# GRAIN SORGHUM BREEDER

GENERAL: Kimberley Research Station is a unit of the Division of Tropical Agronomy, which has its headquarters at Brisbane. The Station is situated at Kununurra in the Ord River valley in the north of Western Australia, and is engaged in research into pastures and crops suitable for the tropical latitudes of Australia. The township of Kununurra services the Ord River Irrigation Area and has a population of about 2,000.

Because of its latitude (16°S) and climate, and excellent field and irrigation facilities, the Kimberley Station is an ideal location for research on tropical sorghums. Breeding of grain sorghum was commenced at the Station in 1970 and considerable progress has been made in developing better-adapted genotypes for the tropical environments of northern Australia.

DUTIES: CSIRO is now seeking a Sorghum Breeder to continue this program. and to collaborate in new studies on physiological factors limiting grain sorghum yields in tropical Australia.

QUALIFICATIONS: A degree in Agriculture or Science, and a Ph.D. or equivalent postgraduate experience in plant genetics, supported by satisfactory evidence of research ability. Experience in plant breeding is essential.

SALARY: Depending upon qualifications and experience, the appointment will be made within the salary range of Senior Research Scientist, \$A13,424 to \$A15,456 p.a. or Principal Research Scientist, \$A16,060 to \$A18,299 p.a. plus local allowances of not less than \$A1,310 (married) or \$A930 p.a. (single).

CONDITIONS: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Six weeks' recreation leave per annum will be granted and this leave may be accumulated for three consecutive years. Fares for travel to and from Perth or equivalent travelling will be provided by the Organization once each two-year period. The area is classified Zone A for taxation purposes.

A house with basic furniture is available for rental.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number: 620/76 should reach:-

The Personnel Officer, Australian Scientific Liaison Office, 64-78, Kingsway, LONDOŇ WC2B 6BD

by the 29th November, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

(1721)

## .CSIRO

# **AUSTRALIA**

# DIVISION OF COMPUTING RESEARCH

CANBERRA, A.C.T.

# RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees-2,100 of whom are research and professional scientists-located in Divisions and Sections throughout Australia.

# **OPERATING SYSTEMS**

**GENERAL:** The Division of Computing Research has a Control Data Cyber 76 Computer (commonly called a 7600) in Canberra. With processor capable of averaging fifteen million instructions per second, central memory exceeding three million characters, disc capacity of twelve hundre dmillion characters, and with substantial expansion capacity, the configuration provides an unsurpassed tool for research and development projects.

The Cyber 76 computer is currently linked to a network of batch terminals by a Control Data 3600 Computer. This will be replaced by a pair of CONTROL DATA model 172 computers, the first of which is scheduled for delivery early in 1975. These "front-end" computers will provide operator control functions, magnetic tape handling facilities and drive the terminal network. It is hoped to evolve a system capable of handling a large number of interactive consoles and batch terminals, with little degradation of source in case of a single CYRER 173 follows. terminals, with little degradation of service in case of a single CYBER 172 failure.

A rapidly expanding network of mini computers at CSIRO research centres is linked by Australian Post Office data services and enables the concentration of interactive and batch work in Canberra. Currently, about thirty batch terminals and about two hundred interactive terminals are connected.

DUTIES: To work as part of a team engaged in research, development and maintenance of operating system software for both the Cyber 76 and the new front-end computers. Members of the team are expected to take some responsibility for day-to-day system maintenance but will also need the ability to undertake original and major projects.

Areas of likely development include the provision of interactive access to the Cyber 76 and front-end computers, job scheduling, archival file storage and connection to communication networks.

**QUALIFICATIONS:** A Ph.D. degree (or equivalent) in computing science, together with demonstrable research ability is essential and previous experience in operating systems work is desirable.

**SALARY:** Appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A10,448-\$A15,456 p.a.

TENURE: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional details, the names of at least professional referees, and quoting Reference Number: 900/248, should

The Personnel Officer Australian Scientific Liaison Office, 64-78, Kingsway, LONDON, WC2B 6BD

by the 29th November, 1974. Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

(1722)

### TEESSIDE **POLYTECHNIC**

Applications are invited for a post of Research Assistant in The Department of Mathematics and Statistics, to carry out research into multistep methods of numerical integration of differential equations.

Applicants must have, or expect to obtain, a good honours degree in mathematics.

The post will be for a minimum of two years at a salary of £1,500 per annum.

Further details and application forms may be obtained from the Staffing Section Teesside Polytechnic, Borough Road, Middlesbrough, Cleveland County TS1 3BA.

(1745)

### JAMES COOK UNIVERSITY OF NORTH QUEENSLAND LECTURER IN BOTANY

Candidates should have a special interest and research experience in some aspect of Plant Genetics although applications will also be considered from those having an interest in some related field provided they are competent to conduct undergraduate courses in Plant Genetics. The appointee will be expected to assist in the general teaching and research activities of the Department. Salary range: \$A9,002 to \$12,352 p.a. plus a locality allowance of \$A142 p.a. for a married male or \$A71 p.a. for a single appointee. Conditions of appointment include F.S.S.U. superannuation, invalid pension scheme, housing assistance, study leave and allowance for travel and removal expenses on appointment. Further details and application forms obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH OPF.

Applications close November 29, 1974. (1669)

### UNIVERSITY OF WALES WELSH PLANT BREEDING STATION

WELSH PLANT BREEDING STATION

Applications are invited for a Scientific Officer support post in the Chemistry Department of the Station to undertake and supervise non-routine analytical work associated with the research programmes in cereal and herbage chemistry.

The qualification required would be a Higher National Certificate in Chemistry or an equivalent qualification, with experience and interest in the use of automated analytical equipment including amino acid analysers.

Salary scale £1,592 to £2,675 per annum plus threshold agreement at present £2.80 per week. There is a non-contributory superannuation scheme and male employees are required to contribute 1½% of salary to the Widows' and Chidren's Pension Scheme.

Commencing salary will be determined by age

Commencing salary will be determined by age

and experience.

Applications by letter only, together with names of two referees, to be sent to the Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Nr. Aberystwyth, Dyfed SY23 3EB on or before November 15, 1974.

### UNIVERSITY OF EDINBURGH EDINBURGH SCHOOL OF AGRICULTURE

### LECTURER IN TROPICAL ANIMAL PRODUCTION

ANIMAL PRODUCTION

Applications are invited for a short-term appointment (3 ot 4 years) of Lecturer in Tropical Animal Production.

The successful candidate will contribute to a new course in Tropical Animal Health and Production by the Centre for Tropical Veterinary Medicine and the School of Agriculture.

Agriculture.

Salary on the scale £2,118 to £4,896 per annum. Superannuation under F.S.S.U.,

Applications should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, from whom further particulars may be obtained. Please quote reference 1042.

M42. The closing date is November 25, 1974. (1736)

### FOURAH BAY COLLEGE UNIVERSITY OF SIERRA LEONE

UNIVERSITY OF SIERRA LEONE
Applications are invited for the post of PROFESSOR AND HEAD OF THE GEOGRAPHY
DEPARTMENT, tenable September 1, 1975. Salary
scale (under review): Le6,000 to Le6,800 p.a.
(Le2=£1 sterling). The British Government may
supplement salary by £2,850 (sterling) p.a. for a
married appointee and £1,854 (sterling) p.a. for a
single appointee (normally free of all tax) and
provide children's education allowances and holiday visit passages. £5.5.U. Family passages;
various allowances; regular overseas leave. Detailed
applications (2 copies), including a curriculum
vitae and naming 3 referees, should be sent by
airmail, not later than November 27, 1974, to the
Secretary University of Sierra Leone. Applicants resident
in U.K. should also send 1 copy to Inter-University
Council; 30/91 Tottenham Court Road, London
WIP ODT. Further particulars may be obtained
from either address. (1679)

### UNIVERSITY OF ZAMBIA

UNIVERSITY OF ZAMBIA

Applications are invited for (a) LECTURESHIP or (b) ASSISTANT LECTURESHIP IN PLANT SCIENCE, School of Agricultural Sciences. Applicants should possess M.Sc. and/or Ph.D. in Agronomy or Crop Physiology, and have teaching and/or research experience in these fields. Appointe will be required to teach the basic courses in Plant Science concerned with tropical pastures, forage crops and other fundamentals of Crop Production. Salary scales: (a) K4,600 to K5,400 p.a. (b) K3,200 to K3,800 p.a. (£1 sterling=K1.50). The British Government may supplement salaries of married appointees at Lecturer level in range £516 to £666 p.a. (sterling) (normally free of all tax) and provide children's education allowances and holiday visit passages. This supplementation is unlikely to apply to single appointees at Lecturer level. Family passages; various alllowances; superannuation and medical aid schemes; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than November 27, 1974, to the Registrar, University of Zambia. P.O. Box 2379, Lusaka, Zambia. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London WIP 0DT. Further particulars may be obtained from either address. (1678)

### UNIVERSITY OF NOTTINGHAM PHYSICS POSTDOCTORAL RESEARCH

ASSISTANT

is required to work on the propagation of very high frequency phonons in solids and liquid helium at 0.1K. Techniques include superconducting motors to move phonon sources and tunnel junction detectors at dilution refrigerator temperatures. Manual dexterity, stamina and physical insight are more important than detailed experience. Salary £2,247 plus threshold.

Applications to Dr A, F. G. Wyatt, Department of Physics, University of Nottingham, University Park, Nottingham NG7 2RD. (1684)

SECTION OF MOLECULAR PHARMACOLOGY

of the UNIVERSITY OF MAINZ GERMANY

RESEARCH ASSOCIATES (Ph D in Biochemistry, Organic Chemistry or Cell Biology)

and TECHNICIANS WITH

MASTERS DEGREE (Biochemist, Organic Chemist or Cell Biologist)

required for well-equipped research laboratory to work on mechanisms of chemical carcino-involving synthetic and/or biochemical work, animal experimentation and/or tissue culture.

or tissue culture.

Salary within the range of £5,000 to £8,000 per annum for the research associate, £3,200 to £6,500 for the technician.

Start of appointment December 1, 1974 or later (some openings April 1, 1975).

Experience in solubilization, purification and study of enzymes and knowledge of German an advantage but not a prerequisite. Detailed applications with the names of referees and giving relevant laboratory experience should be sent to Dr F. Oesch, Biozentrum of the University, Klingelbergstrasse 70, CH-4056 Basel, Switzerland.

# BIOCHEMIST or CELL BIOLOGIST, **SWEDEN**

Pharmacia Fine Chemicals AB, manufacturers of SephadexR and other products for biochemical separations, require a biochemist or cell biologist to work at our headquarters in Uppsala, Sweden.

The successful applicant will join our Scientific Information and Technical Services group. The activities of the group include

- \* the preparation of all kinds of scientific information material
- applications work and laboratory testing of new products
- \* lecturing

but applicants should be prepared for extremely varied work and certain amount of travelling, mostly within Europe.

Applicants should have research experience in biochemistry or cell biology. Clear and accurate expression in the written word is essential with English as the Mother tongue.

This is an important position and carries an appropriate salary. Preferred age 25 to 30.

Write in confidence to:

Mr D. Sweetman Pharmacia (Great Britain) Ltd **Paramount House** 75 Uxbridge Road London W5 5SS

### HAZLETON LABORATORIES EUROPE LIMITED

require a

### BIOCHEMIST or BIOCHEMICAL PHARMACOLOGIST

preferably a Ph.D. with some experience in drug metabolism and/or the use of isolated organ perfusion techniques, to join a team which is studying factors affecting foreign compound disposition and metabolism. The principal area of interest, at present, is tobacco smoke but the scope is expected to extend rapidly into other fields.

Excellent facilities for research are available in well-equipped laboratories set in pleasant rural, but accessible surroundings.

Please write, giving brief details of qualifications and experience to:

The Personnel Officer, (Ref. R.O.e), Hazleton Laboratories Europe Limited,

Harlow Hill,

HARROGATE HG3 1PY.

(1688)

### LEICESTER POLYTECHNIC

SCHOOL OF CHEMISTRY

Applications are invited for the following research ssistantships:

(1) Bio-inorganic chemistry; for studies on the drug penicillamine in relation to Wilson's Disease.

drug penicillamine in relation to Wilson's Disease.

(2) Solid state chemistry, for studies of mass transport in ionic solids.

Applicants should have a good honours degree in Chemistry or equivalent qualification.

For post (1) an interest in analytical inorganic chemistry and/or protein chemistry is necessary. Some experience in one of these fields would be an advantage.

Post (2) requires a competent experimentalist with an interest in radiotracer techniques and/or crystal growth.

Appointments are for three years and commencing salary is £1,824 p.a. Successful applicants holding a Bachelors or Masters degree will be expected to register for a Ph.D.

Intending applicants are encouraged to phone Roger Linford (0533 50181 ext. 2202) for further particulars. Application forms are obtainable from Staffing Officer, Leicester Polytechnic, P.O. Box 143, Leicester LE1 9BH. (1689)

# **AUSTRALIA Public Service of Victoria Ministry for Conservation** PROJECT DIRECTOR

(THREE POSITIONS)

Position No. 1—PORT PHILLIP BAY. REF. No. (H/07) Position No. 2—WESTERNPORT BAY. REF. No. (H/08) Position No. 3—GIPPSLAND LAKES. REF. No. (H/09)

Yearly Salary \$A16,393—SCIENTIFIC OFFICER **\$A16,207—ENGINEER** 

### **Duties:**

Subject to the Director of Environmental Studies, to be responsible for the general direction and co-ordination of the Port Phillip Bay, Westernport Bay and Gippsland Lakes Environmental Studies. To maintain liaison with, and co-ordinate, the activities of the Government, University and other groups participating in such Study. To summarise and report on activities of participating groups and to assist in the application of research activities to environmental management.

### Qualifications:

An approved degree in the physical or biological sciences, or an approved degree in engineering or other qualification admitting to Membership in the Institution of Engineers, Australia, or other appropriate qualification; a higher degree desirable. Demonstrated ability in working in multi-disciplinary groups and proven ability at a senior level to plan, develop and lead inter-disciplinary investigations. Experience in the practical application of research findings to management and a knowledge of the working of Government, University and Industry desirable. Experience in a marine science an advantage.

Separate applications must be submitted for these positions.

Applications quoting appropriate reference number should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Wednesday, November 20, 1974, together with statements of experience and qualifications and date and place of birth. (1742)

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG, SOUTH AFRICA DEPARTMENT OF ANATOMY SENIOR LECTURESHIP IN **HUMAN ANATOMY** 

HUMAN ANATOMY

Applications are invited for appointment to the post of Senior Lecturer in the Gross Anatomy section of the Department of Anatomy, Medical School, Candidates must be capable of teaching General Anatomy, Micro-Anatomy and Living Anatomy to Medical, B.Sc., Physiotherapy and Occupational Therapy, and Nursing students. The possession of a Ph.D., or other higher degree, with or without a medical qualification, is essential. Salary will be determined according to qualifications and experience, and presently falls within the following ranges

Senior Lecturer (2) R10,350 to R11,730. Senior Lecturer (3) R9,315 to R10,695.

These scales are to be improved shortly.

Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy, if eligible.

Intending applicants should obtain the information sheet relating to the post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than November 30, 1974. U.K. applicants may obtain the information sheet from the London Representative, University of the Witwatersrand, 278 High Holborn, London, W.C.I to whom a copy of the application should be sent.

(1682)

### St. Mary's Hospital Medical School Paddington, London W2 1PG

# RESEARCH ASSISTANT

Graduate or chartered engineer with practical experience in Electronics or Applied Physics, and preferably in Bio-Engineering required. Work, supervised jointly by Dept. of Obstetrics and Gynaecology, and Dept. of Bio-Engineering will mainly be involved in development of new techniques for surveillance of foetus in pregnancy and labour. Initial appointment for 3 years,

Appropriately qualified applicants may read for higher degree in Biomedical Engineering. Commencing salary within scale £2,064 to £2,325 p.a. plus £213 L.A. plus threshold. Further details from Dr. R. E. Trotman. Apply, The Secretary.

# **AUSTRALIA Public Service of Victoria Ministry for Conservation Fisheries and Wildlife Division** PROJECT LEADER

(THREE POSITIONS)

Position No. 1—WESTERNPORT. REF. No. (H/04)

Position No. 2—GIPPSLAND LAKES. REF. No. (H/05)

Position No. 3—PORT PHILLIP BAY. REF. No. (H/06)

Yearly Salary \$A14,520

### **Duties:**

To be responsible for the supervision and direction of research activities conducted by the Marine Pollution Studies Section in the Westernport Bay, Gippsland Lakes and Port Phillip Bay Environmental Studies. To assist in the co-ordination of research activities and to maintain liaison with other groups participating in environmental investigations. To prepare reports and recommendations. Other duties as directed.

### **Qualifications:**

An approved degree in Science or an equivalent qualification; preferably a higher degree. Demonstrated ability and extensive

experience in marine ecological research and in the supervision of scientific staff. To be capable of working with multi-disciplinary groups and to have report writing experience.

### Note:

Separate applications must be submitted for these positions.

Applications quoting appropriate reference number should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Wednesday, November 20, 1974, together with statements of experience and qualifications' and date and place of birth.

### QUEENSLAND INSTITUTE OF TECHNOLOGY DEPARTMENT OF CHEMISTRY TECHNOLOGIST DIVISION II QUOTE: V.106/74

SALARY RANGE: \$7,496 to \$10,637 (AUST.) p.a.

MINIMUM QUALIFICATIONS:

(a) A degree in science, applied science or chemical engineering from a University or college of advanced education; or equivalent formal tertiary qualifications.

(b) Experience and skills sufficient to apply advanced knowledge.

EXPERIENCE REQUIRED:

(a) A minimum of five years' technical experience which has been gained in scientific and/or technological laboratories.

An ability to co-operate and work efficiently with other staff.

DUTIES: One or more of the following:

(a) Assist in the development of new experiments for application to the Department's teaching programme, as well as updating existing experiments when required. The teaching programme encompasses inorganic and analytical chemistry, organic chemistry, physical chemistry and chemical engineering/chemical technology.

(b) Provide technical guidance and assistance to staff and students on the operation of equipment associated with the teaching programme.
 (c) Assist in departmental research and service projects.

(d) Prepare reports and recommendations on the above.

Applications quoting position, reference number, and containing full particulars of name, address, telephone number, date of birth, marital status, qualifications, experience and present employment and the names and addresses of at least two referees, should be forwarded to the Registrar, Queensland Institute of Technology, Box 246, P.O., North Quay, Brisbane, Queensland, Australia, by Saturday November 23, 1974. (1723)

### MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH DIVISION OF VIROLOGY

Applications are invited from 'young postdecotoral virologists for a position within a groupconcerned with basic mechanisms of virus
infection using the adenovirus model system. This
post should be of interest to those who have
experience of any branch of molecular biology.
The appointment will be for up to three years
and will be in the salary range £2,412 to £3,636
p.a. according to age and qualifications (plus
London and threshold allowances). Superannuation provision under F.S.S.U. Consideration will
be given to those who may not be available until
the autumn of 1975.

Applications, giving details of qualifications.

the autumn of 1975.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before December 6, 1974. (1699)

UNIVERSITY OF READING DEPARTMENT OF AGRICULTURE AND HORTICULTURE

### ASSISTANT EXPERIMENTAL **OFFICER**

OR

### POSTGRADUATE STUDENT

Applicants should be graduates in Agriculture or other relevant subjects with practical agricultural experience. The person appointed will work under the supervision of Dr. M. J. Bryant on experiments concerned with body condition, long term nutrition and rebreeding of the sow during lactation. Three year project sponsored by the Agricultural Research Council. Further details and application forms, quoting ref: TN82, from Assistant Bursar (Per-sonnel), University of Reading, Whiteknights. Reading RG6 2AH. (1711)

### UNIVERSITY OF READING RESEARCH PROGRAMME: LEAF PROTEIN PRODUCTION

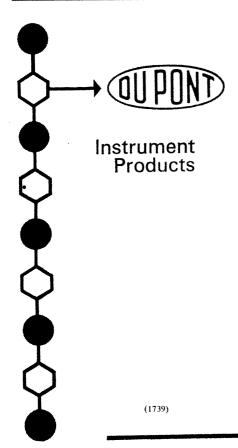

LEAF PROTEIN PRODUCTION

The Department of Agriculture and Horticulture has two vacancies in its programme for the Development of Optimal Agricultural Systems for Leaf Protein Production currently sponsored by the Wolfson Foundation. A RESEARCH OFFICER is required to install and maintain the large scale extraction equipment and to carry out the field scale cropping system trials. The successful applicant is likely to have a qualification in Agricultural Engineering with a strong practical interest in agriculture. Starting salary £1,600 to £2,500 p.a. according to qualifications and experience. A RESEARCH STUDENT is required to carry out factors affecting the accumulation of leaf protein in legume crops. Candidates should hold a First or Upper Second Degree in Agriculture, Agricultural Science or an appropriate Biological Science. The successful applicant will be required to register for a higher degree and the value of the Studentship will be £980 by £50 p.a. Both appointments are for three years and are to commence at the earliest date. Apply, as soon as possible, with the names of two referees to the Professor of Crop Production, Department of Agriculture and Horticulture, Earley Gate, Reading RG6 2AT, from whom further particulars can be obtained. (Ref. M. 51).

### UNIVERSITY OF ZAMBIA

UNIVERSITY OF ZAMBIA

Applications are invited for the post of (a) CHIEF or (b) SENIOR TECHNICIAN IN ANI-MAL SCIENCE, School of Agricultural Sciences. Applicants should possess a B.Sc. in Agriculture, or A.I.S.T., or A.I.M.L.T. or equivalent. Experience in Animal Nutrition and Biochemistry, Histology and/or Pathology, and Small Animal Management advantageous. Salary scales: (a) K3,300 to K4,900 p.a., (b) K2,900 to K3,500 p.a. (£1 sterling=K1.50). The British Government may supplement salaries for married appointees in range £456 to £516 p.a. (sterling) (normally free of all tax) and provide children's education allowances and holiday visit passages. This supplementation is unlikely to apply to single appointees. Family passages; various allowances; superannuation and medical aid schemes; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than November 27, 1974 to the Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia. Applicants resident in U.K. should also send I copy to Inter-University Council, 1909 Tottenham Court Road, London WIP ODT. Further particulars may be obtained from either address. (1681)

# **Biochemist or Clinical Chemist**

# to be **aca Technical Specialist**

This wide-ranging role with the Du Pont Instrument Products Division results directly from the successful introduction of a new concept in clinical chemistry the Automatic Clinical Analyser. Introduced into Europe in 1973, after proven success in the USA, the ACA is capable of analysing a wide range of body fluids and reduces to a minimum the time between sample input and output of data.

After a comprehensive product training in the USA the person appointed will travel extensively in the UK, Scandinavia and the Netherlands, providing specialist support for unit sales, which are increasing. A detailed knowledge of clinical methodology gained through at least two years' laboratory experience is essential, and a knowledge of electronics would be useful. Previous experience in scientific/medical equipment would be helpful.

Starting salary will reflect the seniority of the appointment and benefits which are competitive with the best include a company car and relocation assistance where appropriate.

Please quote reference U.287 when writing or telephoning for an application form to:

T. T. Coulson, Personnel Services Co-ordinator, Du Pont (U.K.) Limited, Du Pont House, 18 Bream's Buildings, Fetter Lane, London EC4A 1HT. Tel: 01-242 9044, ext. 464.

#### STOWE SCHOOL, BUCKINGHAM

Laboratory Technician required to take charge of Biology Laboratory. Salary according to Buckinghamshire Educational Committee recommended scale (at present under revision) of £1,416 to £1,644 according to experience. The successful applicant will be eligible for housing allowance of £120 in addition, or alternatively a house or flats available on a service tenancy with a reduction of £110 from salary. New Laboratories have recently been opened.

Apply to the Senior Science Master, Stowe School, Buckingham, giving names and addresses of two referees. (1690)

#### UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG, SOUTH AFRICA SENIOR LECTURER IN PETROLOGY

PETROLOGY

Applications are invited for appointment to the above post in the Department of Geology. Duties are to be assumed on February 1, 1975.

Applicants should have substantial research experience in the field of igneous and/or metamorphic petrology, a familiarity with experimental petrologic techniques and a Ph.D. or equivalent qualifications. The salary presently attached to the post is in the range R7.245 to R9.315 and increased salary scales are to be introduced shortly. Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy, if eligible.

Intending applicants should obtain the information sheet relating to this post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than November 30, 1974. U.K. applicants may obtain the information sheet from the London Representative, University of the Witwatersrand, 278 High Holborn, London, W.C.1, to whom a copy of the application should be sent. (1683)

### UNIVERSITY OF LONDON INSTITUTE OF NEUROLOGY

Postdoctoral Fellow to join a group investigating the biosynthesis of specific brain proteins during development. Biochemist or Cell Biologist preferred. Salary according to age and experience on the Lecturer scale starting at £2.118. London Allowance, F.S.S.U. Apply to Dr L. Lim, Department of Neurochemistry, Institute of Neurochemy N. 5.8 Exphange Court, London W.C. Department of Neurochemistry, Institu Neurology N, 5-8 Exchange Court, London OPP. Institute of ondon WC2v

### ROYAL POSTGRADUATE MEDICAL SCHOOL

#### JUNIOR TECHNICIAN/TECHNICIAN

required in Department of Clinical Cardiology. This post will involve dealing with patients and some research work. Qualifications GCE 'O' level passes in English, Maths and two Science subjects/ONC or equivalent. Salary according to qualifications and experience.

Applications to the Secretary PRMS Uservices

Applications to the Secretary, RPMS, Hammersmith Hospital, DuCane Road, London W. OHS, quoting ref. no. 2/354 N. (1704)

### UNIVERSITY OF PENNSYLVANIA

Applications are invited for a part-time Visiting Lecturer (one-year appointment) to teach Structural Geology (Spring Term) and Environmental Geology (Fall Term). It is anticipated that the position will be filled for the Spring Term starting mid-January 1975. Salary ranges from \$4,000 to \$6,000. Enquiries should be addressed to R. Ian Harker, Chairman, Department of Geology, D4, University of Pennsylvania, Philadelphia, Pennsylvania 19174, U.S.A. (1706)

### THE UNIVERSITY OF MARYLAND at College Park

Invites Applications for the Position of CHAIRMAN

of the Department of Physics and Astronomy

of the Department of Physics and Astronomy Applicants for the position should have administrative, research and teaching experience. The Department of Physics and Astronomy currently has 150 faculty members, 105 technical staff, and 64 non-technical staff. There are aver 200 undergraduate students and approximately 300 graduate students enrolled in programs leading to the B.S. M.S. and Ph.D. degrees. Nominations, applications and inquiries should be addressed to: P. F. Cumiff, Chairman of the Search Committee Office of the Division of Mathematical and Physical Sciences and Engineering, University of Maryland, Coffege Park, Maryland 20742.

The University is an equal opportunity/affirmative action employer.

### UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF ANATOMY

Applications are invited for the post of Lecturer or "Demonstrator" in the Department of Anatomy. There will be an obligation to engage in the teaching of Topographical anatomy Suitable candidates may be either seeking a career or preparing for the higher examinations in surgery. Salary scale £2.118 to £4.896 plus £213 London allowance. (Starting salary will be at an appropriate place on the scale.) F.S.S.U. benefit will be naid.

appropriate place on the Santa Santa

### **AUSTRALIA**

### **Public Service of Victoria Ministry for Conservation Fisheries and Wildlife Division**

# PROJECT CO-ORDINATOR

(FRESHWATER BIOLOGY), (REF. No. H/10) Yearly Salary \$A13,660

#### Duties:

To co-ordinate the participation of the freshwater fisheries staff in environmental studies. To be responsible for and participate in freshwater biological investigations in such studies and to maintain liaison with Government Departments, Universities and other groups conducting similar investigations. To prepare reports and recommendations.

### Qualifications:

An approved degree in Science or Agricultural Science or an equivalent qualification; preferably a higher degree. Ability to plan, lead and

co-ordinate activities involving multi-disciplinary research groups. Appropriate experience in freshwater biology and proven research ability. Experience in report preparation.

Applications quoting reference number (H/10), should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Wednesday, November 20, 1974, together with statements of experience and qualifications and date and place of birth.

#### INSTITUTE OF CANCER RESEARCH LABORATORIES AT SUTTON, SURREY

LABORATORIES AT SUTTON, SURREY
Division of Tumour Immunology requires Biochemist-Research Assistant to work in Immunochemistry Laboratory, Experience in protein separation techniques desirable. Minimum qualifications, 1st Degree in Chemistry or Biochemistry, or 2 'A' levels in Science subjects. Registration for a higher degree can be considered. Post in Junior Technical Officer scale, salary £1,494 to £2,592 plus London Allowance (£126 p.a. currently under review) plus Threshold.

Apply in duplicate to the Secretary, Institute of Cancer Research, 34 Sumner Place SW7 3NU. giving the names of 2 referees, and quoting ref. 301/B/533.

(1708)

### M.R.C. CLINICAL RESEARCH CENTRE (NORTHWICK PARK HOSPITAL) WATFORD ROAD, HARROW, MIDDLESEX, HAI 3UJ **TECHNICIAN**

for work on the chemical study of some inborn errors of metabolism. The programme is particularly concerned with inherited metabolic diseases in which there appears to be a primary abnormality of organic acid metabolism and it would be suitable for a holder of H.N.C. in chemistry with experience in gas-chromatography. Ref. 123D/2B/4222.

#### **TECHNICIAN**

HECHNICIAN
with A.I.M.L.T. or H.N.C. preferably with experience of scrology, haematology or bacteriology to work in a laboratory concerned with the study of human immunological disease. Ref. 118/2/A21.
Salary for both posts within the range £1,986 to £2,961 plus Threshold increase.
Further details and application forms from Mrs J. Tucker-Bull.

Further details and app Tucker-Bull. Please quote reference.

### ROTHAMSTED EXPERIMENTAL **STATION**

### HARPENDEN, HERTS. AL5 2JQ ASSISTANT STATISTICIAN

to analyse and interpret data from agricultural and other biological experiments using the Station's computer. Degree, H.N.C. or equivalent qualification in mathematics or statistics. Some knowledge of agriculture or biology an advantage. The post is tenable until March 31, 1978 in the first instance and the person appointed will join a small team funded by the Overseas Development Administration to provide a statistical service for agricultural research workers in developing countries.

Appointment in grade of Scientific Officer

Appointment in grade of Scientific Officer (£1.592 to £2.675) plus threshold payments. Starting salary according to qualifications and experience. Superannuation with a contribution of 1½% for family benefits.

Apply in writing to the Secretary giving names and addresses of two referees and quoting reference 245 by November 29, 1974. (1731)

#### FACULTY POSITION

A developing physiology department is seeking individuals with active research programmes and publications in physiology and bio-physics. We are particularly interested in applicants with programmes in renal or endocrine physiology, but all outstanding applicants will be carefully considered. Teaching responsibilities include instruction at the graduate and undergraduate level. Reply to: Will J. Van der Kloot, Chairman, Physiology and Bio-Physics Department, Health Sciences Center, State University of New York at Stony Brook, Stony Brook, New York 11794 U.S.A. The Health Sciences Center is an Equal Opportunity Employer, and applications from members of minority groups and women are welcome. (1730)

### FIELD STUDIES COUNCIL DEPUTY WARDEN

at Juniper Hall Field Centre, near Dorking. Single, good degree in geography, educational qualifications. At least two years professional teaching experience including fieldwork. Wide environmental interests, but special knowledge of urban geography biogeography ad conservation an asset.

graphy biogeography ad conservation an asset.

Besides teaching, duties include administration (staff, student supervision, programme planning, equipment etc.) in consultation with Warden as his second in command. Research opportunities, Salary £1,800 by 75 to £2,025 plus free board and lodging. Appointment Winter 1974/75, closing date for applications November 18, 1974, Further details and application forms from The Director, Field Studies Council, Preston Montford, Montford Bridge, Shrewsbury SY4 1HW. (1735)

### UNIVERSITY OF MANCHESTER

DEPARTMENT OF PATHOLOGY

Applications are invited for a

### POST-DOCTORAL RESEARCH ASSISTANTSHIP

within a group working on the migration of lymphocytes and their role in immune responses. The post is supported by an M.R.C. programme grant to Professor W. L. Ford. The appointment is likely to be for three years.

Experience in some aspect of Cellular Immunology desirable. Salary range p.a.: £2,118 to £4,896. Enquiries may be addressed to Dr W. L. Ford, Dept. of Pathology, University of Edinburgh Medical School. Further particulars and application forms (returnable by November 21) from the Registrar, The University, Manchester. M13 9PL. Quote ref. 227/74/N. (1738)

### **AUSTRALIA**

### **Public Service of Victoria Ministry for Conservation**

# ENVIRONMENTAL MODELLER

REF. No. (H/12)

Yearly Salary \$A13,660

#### **Duties:**

To assess the role of mathematical modelling in environmental investigations and to be responsible for the implementation of modelling techniques. To assist in the co-ordination of environmental studies and in particular, of the interplay between environmental modelling and other aspects of environmental understanding. To maintain liaison with governmental agencies and other groups and to promote an understanding of the use of models as an aid to decision making.

### Qualifications:

An approved degree in the physical or biological sciences, or an approved degree in engineering or other qualification admitting to Membership in the Institution of Engineers,

Australia, or other appropriate qualification; a higher degree desirable. Considerable experience in environmental modelling and demonstrated ability in the application of modelling techniques to inter-disciplinary investigations. Exeperience in the practical application of modelling to conservation or environmental management an advantage.

Applications quoting reference number (H/12), should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Wednesday, November 20, 1974, together with statements of experience and qualifications (1743)and date and place of birth.

### **BIOCHEMIST**

Pesticide Design Chesterford Park is the Research and Development centre for Fisons Agrochemical Division, which is responsible for the invention, development and manufacture of a wide range of chemical compounds for crop protection.

Transfer within the organisation means that we are now seeking an exceptionally able young scientist to contribute biochemically based ideas to our programme of rational pesticide design. The successful candidate will join an experienced team of synthesis chemists, and will also be responsible for supervising a range of biochemical assays to establish rational relationships between structure and activity.

Applicants, who would normally be within the age range 25-30, should be qualified to Ph.D lewel, ideally have some post-doctoral experience, and in addition, the demonstrated

ability to undertake innovative investigation at a high level. Previous experience of pesticide biochemistry is desirable rather than essential.

Starting salary will be commensurate with career record to date, the Company operates a first class pension scheme, and other conditions of employment are amongst the market leaders, Relocation assistance is available where appropriate,

For an application form, please write, quoting serial number 661/197 to:

R. J. Down, Personnel Officer, Fisons Limited, Agrochemical Division, Chesterford Park Research Station, Nr. Saffron Walden, Essex CB10 1XL.

(1746)

### Public Service of Victoria Ministry for Conservation

# ENVIRONMENTAL ECONOMIST

REF. No. (H/11)

Yearly Salary \$A13,660

#### **Duties:**

To be responsible for the development of the most effective means of applying economic theory and practice in environmental studies. To co-ordinate the activities of major environmental studies from an economic viewpoint and, in particular, to assist in the application of economics to environmental management. To prepare reports and to make recommendations.

### Qualifications:

An approved degree with economics as a major; preferably a higher degree. Proven ability to work effectively in multi-disciplinary

scientific investigations and wide experience in the application of economics to environmental investigations. Demonstrated ability at a senior level assisting in the planning and development of inter-disciplinary investigations.

Applications, quoting reference number (H/11), should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002. Australia, by not later than 9.30 a.m. on Wednesday, November 20, 1974, together with statements of experience and qualifications and date and place of birth. (1744)

#### DIRECTOR OF THE PROPOSED CRUMP INSTITUTE OF MEDICAL ENGINEERING AT UCLA

Applications are invited for consideration by the Search Committee for the Director of the proposed "Crump Institute of Medical Engineering" at

Although the proposal for the formal establish-Although the proposal for the formal establishment of this unit is still under study by the Academic Senate and will require Presidential and Regental approval, the search for a highly qualified applicant has been initiated. This position represents a unique opportunity to contribute to the development of the evolving field of "medical engineering", and to establish a major Medical Engineering Programme at UCLA.

Obudifications: A person of asyestional ability.

Qualifications: A person of exceptional ability, accomplishments and international stature is sought whose work and interests bear on the interface between engineering and medical sciences. Demonstrated scientific productivity, leadership and administrative abilities are desirable.

Responsibilities: To administer and direct the proposed Institute.

Salary: Commensurate with qualifications and

Equal Opportunity: The University of California

is an equal opportunity employer.

Send resumé to Dr George Eisenman, Chairman, Search Committee, Department of Physiology, UCLA Medical School, Los Angeles, California (1713)

### UNIVERSITY OF NATAL DEPARTMENT OF PHYSICS

Applications are invited from suitably qualified persons for appointment to the post of

#### **LECTURER**

In addition to normal teaching duties, successful candidates will be expected to take part in the experimental or theoretical activities of one of the research groups of the Department. The fields of interest are:

- Magnetospheric and Atmospheric physics
- Laboratory plasma physics
- Electron Microscope studies of crystal defects

5. Electron Microscope studies of crystal defects 4. Fundamentals of quantum mechanics. Previous experience in one of these fields will be an advantage. The salary will be within the range: R5 520 to R7 935 per annum. A general improvement of salary scales is expected shortly. The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

regulations.

Application forms, further particulars of the post and information on pension, medical aid, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment, are obtainable from the Registrar University of Natal, King George V Avenue, Durban, with whom applications, on the prescribed form, must be lodged not later than February 28, 1975, quoting Ref. Adv. 124/74. (1717)

### LIVERPOOL POLYTECHNIC 1. DEPARTMENT OF CHEMISTRY SENIOR LECTURER

in

### INDUSTRIAL CHEMISTRY/ CHEMICAL ENGINEERING

Applications are invited for the appointment of a Applications are invited for the appointment of a chemical engineer or chemist to join a team involved in the teaching and development of Industrial Chemistry to Honours degree level. The successful candidate will have a first or higher degree in chemical engineering or chemistry and the necessary experience of semi-technical scale plant to exploit fully the extensive facilities in the recently completed Industrial Chemistry Block. Research and consultancy will be encouraged. SALARY: £3,525 to £4,212 p.a. plus threshold

#### 2. SCHOOL OF PHARMACY

#### LECTURER II in PHARMACOLOGY

Applications are invited from graduates in Pharmacy or Pharmacology for the post of Lecturer II in Pharmacology. Applicants should hold a higher degree and relevant post-doctoral experience would be an advantage. The person appointed will be expected to teach pharmacology to honours degree students and to engage actively in research. SALARY: £2.200 to £3,474 p.a. plus threshold Details available from Staff Office, Dept. N. Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool, L3 9RH. (1719)

### UNIVERSITY OF TEXAS MARINE SCIENCE INSTITUTE

MARINE SCIENCE INSTITUTE

The University of Texas Marine Science Institute at Port Aransas is seeking applicants for an appointment, preferably at the ASSISTANT PROFESSOR level, from marine biologists capable of teaching courses in invertebrate zoology of marine organisms and of doing research in the area of physiological ecology. Applicants must have a strong research interest and a commitment to graduate training. Send curriculum vitae and a brief statement of research interests to the Director, The University of Texas Marine Science Institute, Port Aransas, Texas 78373. Affirmative Action/Equal Opportunity Employer. (1726)

### UNIVERSITY OF LIVERPOOL CHAIR OF PSYCHOLOGY

Applications are invited for the Chair of Psychology which will become vacant on September 30, 1975, following the retirement of Professor

30. 1975, following the retirement of Professor L. S. Hearnshaw. The salary will be within the range approved for full-time professional appointments and in any case not less than £6,264 per annum.

Applications, (12 copies), together with the names of three referees, should be received not later than December 6, 1974 by the undersigned, from whom further particulars may be obtained. (Candidates overseas may send one copy only by airmail). Quote ref. RV/293/N.

H. Burchnall.

H. H. Burchnall,

### **BIOCHEMIST**

required to work in clinical fields of abnormal proteins. Opportunities exist for thesis and training in clinical biochemistry.

Salary in accordance with Whitley Council A Scale according to qualifications and experience.

Please send applications with names of two referees to Professor J. R. Hobbs, Department of Chemical Pathology, Westminster Medical School, 17 Page Street, SWIP 2AR. (1733)

### CANCER RESEARCH CAMPAIGN RESEARCH TECHNICIAN (Chemist/Biochemist)

The Molecular Radiobiology group at the Campaign's Laboratory at Mount Vernon Hospital requires assistance with a wide-ranging research programme, investigating fundamental aspects of radiation damage in chemical and biochemical systems and using sophisticated physical techniques. We are seeking a person with proven experimental ability and experience in chemistry or biochemistry: formal academic background is less important. MRC scales apply, e.g. with HNC the post would probably be graded Technician (scale rising to £3,100 inclusive of London allowance and Threshold payments).

Send for further details and application form to: Executive Officer, CRC Gray Laboratory, Mount Vernon Hospital, Northwood, Middx HA6 2RN. (1747)

#### UNIVERSITY OF THE WITWATERSRAND **JOHANNESBURG**

NUCLEAR PHYSICS RESEARCH UNIT FIELD OFFICER:

GEOHYDROLOGIST

A vacancy exists in the Environmental Isotope Group for a suitably qualified person who is fond of an outdoor life and who will be required to work independently and exercise considerable initiative. Applicants should have at least a basic degree in Geology and should have some experience and/or further training in Geohydrology. Familiarity with the sinking and logging of boreholes as well as with geophysical techniques such as resistivity and self-potential will be useful.

Salary will be determined according to quali-

Salary will be determined according to qualifications and experience, and falls within the following ranges:

Senior Research Officer: R7245 to R9315 Research Officer: R5520 to R7935

Improved scales are to be introduced shortly.

The appointment will be for three years in the first instance, with the possibility of renewal.

Applications should reach the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, not later than November 30, 1974. A copy of the application should be sent to the London Representative, University of the Witwatersrand, 278 High Holborn, London WC1

# **Head of Theoretical Physics Group**

Applications are invited from theoretical physicists for the position of Head of the Theoretical Physics Group at Daresbury Laboratory, where members of the Group work in close collaboration with Universities using the Laboratory.

The Group is expected to play a key role in ensuring the effectiveness of the Laboratory's programme. This, at present, is in the fields of high energy physics, synchrotron radiation and computing, but a new major nuclear structure facility is under construction and the construction of a major purpose built source of X-ray and ultra violet synchrotron radiation is under urgent consideration by the Science Research Council.

The successful applicant will be expected to lead a team which will engage in research supporting the experimental programme at the Laboratory Salary will be assessed according to qualifications and experience, but is expected to be within the scale £6,700 to £7,750 per annum.

CLOSING DATE: November 30, 1974.

Please write or telephone Warrington 65000 Ext. 467 for an application form quoting reference DL/529/T to:—

(1727)

Personnel Officer Science Research Council Daresbury Laboratory, Daresbury, Warrington WA4 4AD

### FELLOWSHIPS AND **STUDENTSHIPS**

#### UNIVERSITY OF CALGARY DEPARTMENT OF CHEMISTRY BIOCHEMISTRY GROUP

Applications are invited for the position of **POSTDOCTORAL** RESEARCH FELLOW

commencing early in January 1975. Research will

commencing early in January 1975. Research will be concerned with the structure-function relationship of (1) proteolytic enzymes from Anthozoa; or (2) extracellular enzymes produced by thermophilic fungi.

The initial appointment would be for one year with provision for a second year. Salary according to NRC regulations (\$8,700 per annum).

Application with curriculum vitae and names of two referees to:

Dr K. J. Stevenson

Department of Chemistry
Biochemistry Group
University of Calgary
Calgary, Alberta, Canada
T2N 1N4. (1540)

(1540)

### THE ROYAL SOCIETY

Bruno Mendel Travelling Fellowships

Applications are invited for Bruno Mendel Travelling Fellowships up to a maximum of £5,000 per annum tenable for periods of up to 1 year from October 1, 1975 to enable postgraduate candidates to carry out experimental medical research in the United Kingdom. The Netherlands or Israel. Candidates should be normally resident in one of these three countries and should not already be living in the country which they propose to visit.

Application forms, receivable by January 15, 1975, and further details are available from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SWIY 5AG (1693)

### NEW ZEALAND

### UNIVERSITY OF CANTERBURY CHRISTCHURCH

### POSTDOCTORAL FELLOWSHIP IN CRYSTALLOGRAPHY

IN CRYSTALLOURATTI

Applications are invited for a one-year appointment to assist research aimed at relating the structural details of model compounds to the chemistry of oxygen transport in haemoglobin. The emolument will be NZ\$7,000 per annum. Further particulars, and Conditions of Appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH 0PF.

Applications close on November 30, 1974. (1694)

THE CITY UNIVERSITY Department of Chemistry

### POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Research Fellowship for work on the direct amination of hydrocarbons in collaboration with Dr R. G. Coombes and Mr B. O. Field. The appointment (Salary £2,118 plus Threshold Payments plus London Allowance with F.S.S.U. benefits) is tenable for one year from an early date to be arranged by agreement and may be renewable.

Applicants should be good experimentalists with backgrounds in either organic or inorganic chemistry or have experience of heterogeneous catalysis.

Applications giving a curriculum vitae and naming two referees, as

soon as possible, please to:
Dr R. G. Coombes,
Department of Chemistry,
The City University,
St John Street, London ECIV 4PB. (1737)

### TWO POSTDOCTORAL FELLOWSHIPS IN THE EARTH AND PLANETARY SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites scientists interested in any field of the earth and planetary sciences to apply for the following Fellow-

Two Post-Doctoral Fellowships, each awarded for a peroid of one year (extendable to two years in special instances) beginning in September, 1975, with a stipend of \$12,000 per annum. Completed applications are to be returned by February 15. Application forms may be obtained by writing to the Director, Lamont-Doherty Geological Observatory, Palisades, New York, 10964.

Award announcements will be made March 31, 1975.

(1652)

### THE UNIVERSITY OF HULL

DEPARTMENT OF PLANT BIOLOGY Applications are invited for the post of

### POSTDOCTORAL FELLOW IN PLANT BIOCHEMISTRY

IN PLANT BIOCHEMISTRY
to work with Dr. D. R. Threlfall on the nature
and properties of the enzymes involved in the
biosynthesis of vitamin E and related compounds
by higher plants and micro-organisms.
The post is financed by the S.R.C. and is
tenable until October 31, 1975.
Salary (excluding threshold payments) will be
on the scale £2,226 by £114 to £2,340 by £72 to
£2,412, plus F.S.S.U. benefits.
Applications giving details of age, qualifications
and experience together with the names of two
referees should be sent to Dr. D. R. Threlfall,
Department of Plant Biology, The University
Hull HU6 7RX, from whom further particulars
may be obtained.

### UNIVERSITY OF LEICESTER

DEPARTMENT OF ENGINEERING Applications are invited for a post of either

### RESEARCH FELLOW or EXPERIMENTAL OFFICER

on an SRC-supported two-year research project into high current-density electrochemical machining with molten salt electrolytes.

Applicants should have either a higher degree or at least two years postgraduate experience, or a first degree, respectively: corresponding salary in the range £2,118 to £2,757 or £1,650 to £2,178 plus threshold.

Further details and application forms may be

of the range £2,118 to £2,777 of £1,630 to £2,170 plus threshold.

Further details and application forms may be obtained from the Head of the Engineering Department, The University, Leicester LE1 7RH (Ref. RF3). Informal enquiries to Mr. H. E. Freer or Dr. A. C. Baxter. (1696)

### POSTDOCTORAL FELLOW OR RESEARCH ASSOCIATE

Available immediately for research into laboratory culture and studies of larval blackflies in conjunction with the program on biocontrol. Salary commensurate with experience and qualifications. Send application etc. to Dr. M. Laird, Director, Research Unit on Vector Pathology, Memorial University of Newfoundland, St. John's, Newfoundland. (1673)

#### UNIVERSITY OF BATH Applications are invited for RESEARCH STUDENTSHIP

supported by S.R.C. for research into plant steroids, as part of an existing programme, Gradu-ates in pharmacy, botany and biochemistry should

Please write with full details to Dr. R. Hardman School of Pharmacy & Pharmacology, The University, Bath, BA2 7AY. (1675)

### THAMES POLYTECHNIC

SCHOOL OF CHEMISTRY

### RESEARCH STUDENTSHIP

Applications are invited for appointment to a research studentship in the field of Corrosion. The appointment will initially be for two years renewable for a third.

The work will involve the study of various inhibitors in their protective action on steel in corrosion media, in collaboration with Atlas Products and Services Limited.

The candidate should hold a 1st or 2nd Class Degree in Chemistry or Metallurgy or an equivalent qualification. The successful applicant will be encouraged to register for the degree of M.Phil. or Ph.D. (C.N.A.A.).

Salary: £1,544 by £55(2) to £1,654 pius payments under the threshold agreement

Further particulars and form of application may be obtained from the Secretary, Thanses Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by November 5, 1974. (1697)

### GILLETTE INTERNATIONAL RESEARCH FELLOWSHIP IN PHYSICS

UNIVERSITY OF SUSSEX, ENGLAND APPLICATIONS ARE INVITED FOR AN INTERNATIONAL POST-DOCTORAL RESEARCH FELLOWSHIP

set up by the Gillette Company to promote the international exchange of scientific and technical workers. The present Fellowship is tenable in the School of Mathematical and Physical Sciences of the University of Sussex under the direction of Professor M. W. Thompson.

Applicants should hold a higher degree, or have had 3-4 years post-graduate research experience. This Fellowship is open to nationals of the U.K., other Western European countries or the United States, or Canada.

The Fellow will be expected to undertake studies of the interaction of accelerated ion beams with solids or the generation of ion beams for materials technology. Applicants may submit their own proposals for a programme of work, although the University cannot guarantee to accept them. It is expected that the results of the work will be published.

The Fellowship will be for one year, in the first instance, with the possibility of renewal for a further year and will carry a remuneration of about £2,800 per annum. Applicants should be able to take up the Fellowship during 1975.

Applications giving full personal particulars including curriculum vitae and the names and addresses of two academic or technical referees, should be sent to:

The Secretary,
International Research Fellowship Committee.

International Research Fellov Gillette Research Laboratory. 454 Basingstoke Road, Reading, Berkshire, England.

Closing date for applications January 31, 1975

(1725)

### UNIVERSITY OF LEEDS DEPARTMENT OF PHYSICAL CHEMISTRY

Applications are invited for the post of RESEARCH FELLOW

work with Professor P. Gray and Dr. A. Clifford.

to work with Professor P. Gray and Dr. A. A. Clifford.

The person appointed will work on the measurement of the diffusion rates of hydrogen atoms in gases, using the technique of resonance fluorescence. Applicants should hold a Ph.D. degree and have experience of research in a related field. Salary on the scale £2,118 to £2,412.

Appointment will be for one year in the first instance, with possible renewal for a further year. Applications to Dr. A. A. Clifford, Department of Physical Chemistry, the University, Leeds LS2 9JT, by November 30.

#### CITY OF LONDON POLYTECHNIC SIR JOHN CASS SCHOOL OF SCIENCE AND TECHNOLOGY

#### RESEARCH POSTS IN PHYSICS

Applications are invited for the following posts tenable immediately for a duration of three years, A Research Assistantship for laser light scattering from liquids and polymers, Salary £1,690 by £55 (2) to £1,800 (including threshold payments).

(2) An S.R.C. C.A.S.E. Research Studentship for study of colloidal clay particles.

Applicants should have a good 1st degree, M.Sc or M.Phil in a relevant science and will be required to register for a higher degree.

Applications forms and further details from the Secretary of the Physics Department, City of London Polytechnic, Jewry Street, London ECS1 2EY (Tel No. 01-283 1030 Ext. 309). (1670)

### POLYTECHNIC OF THE SOUTH BANK DEPARTMENT OF PHYSICS POSTDOCTORAL RESEARCH **FELLOW**

Applications for the above post are invited from suitably qualified candidates to take part in a programme of work based on the application of nuclear techniques, including the use of fast neutron and charged particle beams, to problems in proteins and the suitable problems. in materials analysis

in materials analysis.

Further details of the work currently being carried out in the department and of the conditions of appointment may be obtained from:

Mr. A. J. L. Collinson,
Head of Department of Physics,
Polytechnic of the South Bank,
Borough Road, London SEI 0AA.
Tel: 01-928 8989 Ext. 2160.

(1671)

### THE HEBREW UNIVERSITY OF **JERUSALEM**

#### THE FACULTY OF SCIENCE

Applications are invited for Postdoctoral Fellow-ships for the academic year 1975-1976 In the Fields of Mathematics, Physics, Chemistry, Life & Earth Sciences

The applicant is required to submit his applica-tion (in letter form) before December 1, 1974, together with his list of publications and curriculum vitae, containing details of his marital status, to the Chairman of the Institute, in which he is interested to carry out his research. Applications for post-doctoral research in Earth Sciences should be submitted to the appropriate Head of Department, i.e., Geology, Geography or Atmospheric Sciences. All applicants are requested to address copies of their correspondence to the Dean, Faculty of Science. Science.

The applicant is further required to arrange for

The applicant is further required to arrange for at least two letters of recommendation, from persons well-acquainted with his personal and academic record, to be directed to the relevant Chairman, or Head of Department: these recommendations to reach their destination by December 1, 1974.

The fellowship provides for a tax-free salary ranging from approximately IL.14,000 to IL. 16,000 (dependent on the candidate's marital status), which is payable in eleven monthly instalments. The faculty usually allows for a single air-ticket to Israel, and a similar allowance is made if the candidate leaves Israel on completion of his tenure as post-doctoral fellow.

The fellowship is intended primarily for persons

his tenure as post-doctoral renow.

The fellowship is intended primarily for persons who attained their degree in very recent years, and for those who will complete all requirements for the Ph.D. degree before the autumn of 1975.

(1651)

### UNIVERSITY OF KENT AT CANTERBURY RESEARCH FELLOWSHIP IN PHYSICS

Applications are invited for a post-doctoral Research Fellowship supported by the Science Research Council to join a group using laser light scattering techniques for the study of molecular motions in simple liquids and solids. Experience in high resolution optical spectroscopy or computerised data analysis would be an advantage but is not essential. Salary in the range £2.118 to £2.412. Application forms and particulars may be obtained from the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH, to whom completed applications should be returned by November 13. Please quote ref. A72/74.

### POSTDOCTORAL FELLOWSHIPS

Subject to approval of funds postdoctoral opportunities are anticipated in the following areas of biting fly research program on biocontrol; 1. Ecology of larval blackflies; 2. Laboratory studies and culture of pathogens and parasites of biting flies, and 3. Field surveys for biting fly pathegens and parasites. Send application etc. to Dr M. Laird, Director, Research Unit on Vector Pathology, Memorial University of Newfoundland, St. John's, Newfoundland. (1707)

### SHEFFIELD POLYTECHNIC RESEARCH FELLOW IN BIOLOGICAL SCIENCES

Applicants should be experienced in microbial biochemistry, with particular reference to biological recycling of industrial and town wastes and effluents.

The initial appointment will be for three years with the possibility of extension for a further two years.

Salary Scale: Senior Lecturer Grade £3,525 to £3,945 (bar) to £4,212 Plus Threshold

Application forms and further details are obtainable from the Personnel Officer, Sheffield Polytechnic, Halfords House, Fitzalan Square, Sheffield S1 2BB, to whom completed forms should be returned as soon as nossible (1718)

### **GRANTS & SCHOLARSHIPS**

### UNIVERSITY OF OXFORD ST. CATHERINE'S COLLEGE

SI. CATHERINE'S COLLEGE

The College proposes to award one Graduate Scholarship, tenable for one year in the first instance, renewable for a second, and in exceptional circumstances for a third year, from October 1, 1975. The maximum value of the Scholarship is £985 p.a. plus approved University and College fees. The award is open to graduates (men and women) of any university in the U.K. (excepting Oxford), Canada, U.S.A., Australia and New Zealand who intend to work for higher degrees in any subject at Oxford, Further details may be obtained from the Senior Tutor, St. Catherine's College, Oxford, and applications will close on March 31, 1975. (1712)

#### **BUSINESS OPPORTUNITIES**

### TOP COMMISSION SOLE AGENTS

A Professional Electronic Company producing laboratory stabilised power supplies of advanced design requires Agents in several parts of the world.

Individuals or companies of exceptional technical and market knowledge capable of exploiting the profit potential of a high commission line are invited to contact Box No. 1397, Nature, T. G. Scott & Son Ltd.. 1 Clement's Inn, London WC2A 2ED. (1397)

# THE INTERNATIONAL SOCIETY OF DIFFERENTIATION

(President J. Brachet) announces the

### SECOND INTERNATIONAL CONFERENCE ON DIFFERENTIATION

to be held in Copenhagen, September 8—12, 1975

The conference will include sessions on: Cell surface and differentiation.

Aspects of cell division and differentiation.

Carcinogenic disorders and differentiation.

Communications on other topics, especially controversial aspects of cell differentiation are invited.

Conference Committee Members:
M. Abercrombie. E. J. Ambrose, R. Auerbach, J. Brachet, A. Braun, D. A. L. Davies, B. Ephrussi, W. Franke, H. Holtzer, F. Jacob, N. K. Jerne, C. Kafiani, G. Klein, R. Levi-Montalcini, A. Lwoff, R. G. McKinnell, C. L. Markert, B. Mintz, N. Müller-Bérat, C. Pavan, B. Pierce, C. Rosenfeld, S. Spiegelman, D. Tarin. G. Tocchini-Valentini, S. Toivonen, G. Tomkins, D. Viza, D. Yaffe, T. Yamada.

Further information from:
The Conference Secretariat:
Dr. Nicole Müller-Bérat,
Statens Seruminstitut,
Amager Boulevard 80
Copenhagen S,
Denmark,

or the I.S.D. Secretariat: Dr. Dimitri Viza, Laboratoire d'Immunobiologie, Faculté de Médecine Pitié-Salpétrière, 105 boulevard de l'Hôpital, 75634 Paris Cedex 13, France.

Deadline for submitting abstracts: 15th May, 1975.

In 1970 the Miles Yeda group pioneered the introduction of commercially available lectin: CONCANAVALIN A. Our commitment to filling your needs and continuing two-way dialog with the research community has resulted in the availability of additional lectins. Dr. Moshe Rashi, working with colleagues at the Weizmann Institute, has developed and prepared a wide range of high purity lectins. He is actively interested in learning of your interest in our existing line of new products. For a comprehensive bibliography on Lectins, a brochure on our available products or if you have a specific interest in any particular application call or write to the office nearest you.

### **CELL CYCLE CONTROLS**

edited by GEORGE M. PADILLA, IVAN L. CAMERON and ARTHUR M. ZIMMERMAN

This volume brings together the research and critical assessment of some 40 international investigators studying the control mechanisms of the cell cycle. It contains recent experimental data on key questions: the role of the surface membrane in the cell cycle; protein

synthesis and DNA replication; control of periodic enzyme synthesis in eukaryotic cells; the relationship between initiation and rate of chain growth in DNA replication; the involvement of microtubules and filaments in cell division. 1974, 384 pp., \$16.00/£7.70.

### NUMERICAL METHODS IN WEATHER PREDICTION

by G. I. MARCHUK translated by K. N. TRIROGOFF and V. R. LAMB translation edited by A. ARAKAWA and Y. MINTZ

CONTENTS: Introduction: Basic Equations of Atmospheric Dynamics. The Quasigeostrophic Approximation. The Splitting-Up Method. The Splitting-Up Method Applied to the Weather Prediction Equations. A Weather Prediction

Scheme Based on Conservation Laws, Humidity Prediction in the Atmosphere. The Radiation Field in Weather Prediction. Objective Analysis of Meteorological Fields. 1974, 288 pp., \$21.50/£7.00.

# GENETIC AND ANTHROPOLOGICAL STUDIES OF OLYMPIC ATHLETES

edited by ALFONSO L. DE GARAY, LOUIS LEVINE and J. E. LINDSAY CARTER

Most people went to the 1968 Olympic Games in Mexico City to watch and cheer. The scientists who have prepared this lavishly detailed volume had something else in mind as well: to make the most comprehensive study ever of the biology of athletes—especially their genetic and anthropological

characteristics. The restuling work is remarkable not only for its depth of treatment, but also for what is perhaps the first such study of women athletes, and a unique analysis of racial differences within specific athletic events. 1974, 250 pp., \$14.50/£6.95.

### **ACIDIC PROTEINS OF THE NUCLEUS**

edited by IVAN L. CAMERON and JAMES R. JETER, Jr. A Volume in the CELL BIOLOGY Series

CONTENTS: DNA-Binding Proteins and Transcriptional Control in Prokaryotic and Eukaryotic Systems Isolation of the Nuclear Acidic Proteins, Their Fractionation, and Some General Characteristics. Extraction and Characterization of the Phenol-Soluble Acidic Nuclear Proteins. Acidic Nuclear Phosphoproteins. Characterization of Nuclear Phosphoproteins in

Physarum Polycephalum. The Nuclear Acidic Proteins in Cell Proliferation and Differentiation. Nonhistone Proteins of Dipteran Polytene Nuclei. Acidic Nuclear Proteins and the Cell Cycle. The Role of Nuclear Acidic Proteins in Binding Steroid Hormones. The Role of Acidic Proteins in Gene Regulation. 1974, about 300 pp., in preparation.

### Second Edition

### THE PHYSIOLOGY OF INSECTA

edited by MORRIS ROCKSTEIN

FROM A REVIEW OF VOLUME 1:

"... Now the series is being completely reworked. Besides an updating of the information, there will be an expansion of the treatise to six volumes. Chapters on bioluminescence, photoperiodism and circadian rhythms, pheromones, and other new topics are to be included in the new edition. Each chapter presents a detailed overview of a particular aspect of insect physiology by an authority in that field and is written so as to be comprehensible to people outside the field. . . . In its new edition this series will be of value to researchers and students in all areas of insect biology."—SCIENCE.

VOLUME 1/1973, 544 pp., \$38.00/£17.50/Subscription price \$32.00.

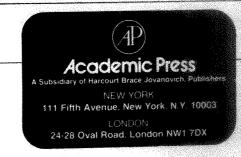

VOLUME 2/1974, 608 pp., \$38.00/£18.25/Subscription price \$32.00.

VOLUME 3/1973, 540 pp., \$38.00/£17.50/Subscription price \$32.00.

VOLUME 4/1974, 476 pp., \$34.50/£16.55/Subscription price \$29.50.

VOLUME 5/1974, 682 pp., \$44.00/£21.10/Subscription price \$37.50.

VOLUME 6/1974, 560 pp., \$43.00/£20.65/Subscription price \$36.55.

### IMMUNOLOGICAL TOLERANCE

Mechanisms and Potential Therapeutic Applications (Proceedings of an International Conference held at Brook Lodge, Augusta, Michigan, April 27—May 1, 1974)

### edited by DAVID H. KATZ and BARUO BENACERRAF

SESSIONS: T Cell Tolerance. B Cell Tolerance. Mechanisms of B Cell Tolerance. Mechanisms of T Cell Tolerance. Activity of Suppressor Cells as a mechanism of Tolerance. Suppres-

sive Activity of Antibody and Antigen-Antibody Complexes. Summary and Potential Therapeutic Applications. 1974, 660 pp., \$21.00/£10.10.

### INTRAUTERINE DEVICES

Development, Evaluation, and Program Implementation (Proceedings of a Workshop on Advances in IUDs held at the Battelle Seattle Research Center, Seattle, Washington, October 18—20, 1973)

edited by ROBERT G. WHEELER, GORDON W. DUNCAN and J. JOSEPH SPEIDEL

CONTENTS: The IUD: An Overview. The Identification and Introduction of Improved

IUDs. Prescription of IUDs. Inert IUDs. Bioactive IUDs. Appendix. 1974, in preparation.

# PLASTICITY AND RECOVERY OF FUNCTION IN THE CENTRAL NERVOUS SYSTEM

edited by DONALD G. STEIN, JEFFREY J. ROSEN and NELSON BUTTERS

The chapters comprising this volume comprehensively discuss the nature and scope of recovery of function after CNS damage. They cover, not only what is now known on this relatively new area of CNS plasticity, but also almost all the methodological and theoretical approaches to its study. Topics discussed include: historical concepts of localization of function and its relationship to CNS plasticity, according to current concepts; Original research on developmental plasticity

in the CNS, emphasizing morphological and anatomical changes underlying plasticity (or its lack) in the developing nervous system; behavioral recovery in developing organisms—including several theories to account for retention of function in neonatal specimens tested long after the damage has been inflicted; the process of recovery of function in adult organisms; and clinical examples of recovery (or lack of it) in human beings. 1974, 528 pp., \$19.50/£9.35.

### ENERGY, ECOLOGY, AND THE ENVIRONMENT

by RICHARD WILSON and WILLIAM JONES

CONTENTS: Introduction. Man's Energy Resources. Energy Demand and Cost. Thermal Pollution. Nuclear Fission and Fusion. Comparison of Hazards in Life. Environmental Problems at the Sources. Air Pollution. The Radiation Hazard to Man. Accidents and

Sabotage. Transportation of Energy and Wastes. Energy Converters. Waste Disposal and Fuel Reprocessing. Regulation of the Energy Industry. Energy Conservation. Summary. 1974, 320 pp., \$4.95/£2.40.

### ETHYLENE IN PLANT BIOLOGY

by FREDERICK B. ABELES

CONTENTS: Introduction. Chemistry and Analysis of Ethylene. Physiology and Biochemistry of Ethylene Production. Hormonal and Herbicidal Regulation of Ethylene Production. Stress Ethylene. Growth and Developmental Effects of Ethylene. Phytogeron-

tological Effects of Ethylene. Regulation of Metabolic and Physiological Systems by Ethylene. Ethylene analogs and Antagonists. Mechanisms of Ethylene Action. Air Pollution and the Ethylene Cycle. 1973, 314 pp., \$18.50/£8.50.

### **CONTEMPORARY BIOLOGY SERIES**

### The Mechanism of Photosynthesis

C. P. WHITTINGHAM

This book puts into perspective current research on the biochemistry of photosynthesis and provides the reader with a good general view of existing knowledge of the process. The historical basis and experimental evidence for each current concept is emphasized throughout.

Cloth £3.80 net Paper £1.90 net

### **Principles of Animal Physiology**

Secona Edition

D. W. WOOD

Unlike most introductory texts in animal physiology this work makes no distinction between 'general' and comparative' physiology. Emphasis is laid on modern developments in cellular physiology, but up-to-date accounts of the physiology of whole animals are also included. Especially important is the full coverage given to fields related to animal behaviour—the physiology of nerve and muscle and of co-ordination.

Cloth £5.70 net Paper £2.85 net

### The Biology of Lichens

Second Edition

MASON E. HALE

This is the only unified treatment of lichens available. Emphasis is placed on current areas of research including ultrastructure, physiology, biochemical taxonomy, ecology and chemistry. Recent work with the electron and scanning electron microscope provides much of the new edition's material on fine structure and ultrastructure.

Cloth £5.50 net Limp £2.75 net

### A Geology for Engineers

Sixth Edition

F. G. H. BLYTH and M. H. de FREITAS

The issue of a sixth edition of this book bears witness to the esteem in which it is held by generations of engineers and geologists. Under joint authorship the book has been extensively revised to include much new information and all units, except those quoted from actual case histories conform to SI.

Cloth £7.50 net Paper £3.75 net

### **Pests of Field Crops**

Second Edition

F. G. W. JONES and MARGARET G. JONES

The wide range of topics so competently presented in this book is unrivalled by other publications. Whilst the form of the first edition text is retained, it has been substantially revised to incorporate much new information, particularly in relation to recent advances in our knowledge of the nature of pesticides.

Cloth £8.50 net

### Towards an understanding of the Mechanism of Heredity

Third Edition

H. L. K. WHITEHOUSE

'The first edition of this book, published in 1965, has been a considerable success as a textbook for students not only of genetics but also other branches of general biology. . . . The second edition, like the first, is an encyclopaedic storehouse of information.'

Nature

Cloth £7.50 net Paper £3.75 net

### The Ecology of Natural Resources

I. G. SIMMONS

The natural resources of the earth are readily or potentially available for consumption. The planet is unlikely, however, to continue supplying materials and providing valued environments unless a just and proper balance is found in their exploitation and conservation. Ian Simmons analyses the nature of this balance and examines the social and behavioural constraints that may be necessary to achieve it. He examines a wide range of contemporary resources, from wilderness to energy and provides a perspective on the views both of those who foresee imminent doom and of those who see solutions mainly in the terms of continued technological development.

Cloth £8.00 net Paper £3.85 net

### Introduction to Marine Geology and Geomorphology

CUCHLAINE A. M. KING

During the ten years since the first edition of Oceanography for Geographers (published in the USA as Introduction to Oceanography) was published, there has been an explosive development in nearly all aspects of the subject. So much has been written concerning this aspect of oceanography that it has been necessary for the author to prepare the new edition of Oceanography for Geographers as two separate books, both of which are almost entirely new.

This is the first.

The text provides a most detailed introductory account of the morphology and development of the ocean basins. Its publication coincides with a rapid expansion in the subject following the recently accelerated exploitation of marine resources.

Cloth £9.80 net Paper £4.90 net

### Introduction to Physical and Biological Oceanography

CUCHLAINE A. M. KING

The physical aspects considered in this book include an introduction to the character of ocean water and its circulation in the form of surface currents and deep wave movements. The subjects of tides, and the various waves that disturb the surface of the ocean are considered and the biological aspects of oceanography form a major and topical theme through the second half of the volume. An appendix concerned specifically with the increasingly complex legal aspects of ocean usage has been prepared by Edgar Gold, an expert in oceanic law, and forms a valuable addition to the volume.

Cloth £11.00 net Paper £5.50 net

### Environmental Remote Sensing: Applications and Achievements

Edited by ERIC C. BARRETT and LEONARD F. CURTIS

Recognition of the crucial importance of environmental management has been accompanied by a significant growth of interest in the potential of remote sensing. This collection of essays discusses a wide range of actual and potential applications of remote sensing techniques in environmental studies. The concern of each contributor has been to review the present status of a sector of remote sensing technology, to describe and evaluate projects currently under way (many of them interdisciplinary) and to indicate future developments and research, including the difficulties inherent in particular techniques.

#### Guide to authors

\*Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to ea if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

**References** are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

- (i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.
- (ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the World List of Scientific Periodicals, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-bepublished volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of Nature. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

### **Support for Trieste**

THE International Centre for Theoretical Physics in Trieste was established in the early sixties in order to provide a base to which young competent theoretical physicists from developing countries could go occasionally for intellectual exchanges and advanced research. An extensive report on the centre's activities was given earlier this year in Nature of March 22. Much of the early, and indeed continuing success has been due to the manipulations of Abdus Salam, then Pakistan's delegate to the International Atomic Energy Agency (IAEA) and Paolo Budini, professor of physics at the University of Trieste. These two managed to persuade IAEA, the city of Trieste and the Rome government to support a project which encountered a lot of cynicism and disbelief from the scientifically advanced countries. Many felt that helping physicists from technologically backward countries to pursue esoteric research was wasteful of scarce manpower resources. Salam vigorously attacks this point of view by pointing to the alternative open to bright young physicists who discover the exhilaration of research emigration. In a developing country there may be a mere handful of highly skilled academic physicists', he declares, 'They each play a major role in the development of that country's technology, universities and intellectual life. Better far to provide somewhere to recharge their batteries than simply to let them emigrate.'

In the early days the city provided a total of \$1 million and IAEA gave \$55 thousand annually. UNESCO started with \$27 thousand annually and in 1970 moved up to a fuller level of participation. At present the Italian government gives \$350 thousand, UNESCO, the UN Development Project and IAEA each give \$200 thousand.

UNESCO support, although modest at first, is, at least formally, ten years old and UNESCO pursues a policy of regarding its financial aid as no more than seed money to get an institution going. After ten years, according to its protocol, the centre should be able to stand on its own feet and find sources of money elsewhere. This is a sound policy for most establishments that UNESCO supports which can go to a specific national government and ask for money. But it is less sound where an institute is used by 90 different nations, the majority poor.

The official British line, which will lead to the delegation expressing their concern at UNESCO this week, is that after ten years there are other deserving projects which could use the \$200 thousand—itself a large slice of the total UNESCO basic science budget of \$1.5 million—and so the support should be re-examined. And a 34% growth rate, they say, is out of line with other growth rates in UNESCO. There is no immediate pressure on Trieste, as it is not proposed to cut funding at once; however in the long run it is clear that the British delegation want Trieste to look elsewhere for their money. Other countries do not see it that way, indeed

one or two diplomat-scientists privately express the view that Britain is making herself look foolish by such a gesture at this time. With inflation posing terrible problems for all educational institutions and the rest of the world apparently unready to rock the boat, what causes Britain to take a mayerick line?

Partly, no doubt, there is a feeling in the Ministry of Overseas Development (which concerns itself with UNESCO) that the way to help developing countries is through more 'relevant' research. But the prime mover in this affair seems to have been a distinguished scientist himself—Sir Harold Thompson, chairman of the Royal Society UNESCO scientific committee.

It had been clear for some time that Sir Harold intended to urge UNESCO to withdraw from Trieste. His views on the centre (*Nature*, 243, 136; 1973) were that it was successful, but he did express some concern that international laboratories were being backed by 'well organised pressure groups'. Yet it was not until May 1974 that a group of physicists and mathematicians familiar with the centre was convened by the Royal Society to put their point of view to Sir Harold.

The meeting seems to have been unsatisfactory in that there was no real meeting of minds over the issue. The group, pressure group that it doubtless was, left dissatisfied and with the feeling that the nature of the Trieste centre and the problems that it faces had been barely understood. Trieste's mathematical activities—a recent development—had hardly been appreciated.

As a result, Britain's official viewpoint cannot really be said to be representative of the views of British physicists and mathematicians and seems as much as anything to have emerged from one man's opinion.

The growth rate of 34% quoted by those who urge re-examination is a mystery. It is a real growth rate, we were assured. And yet UNESCO's contribution has risen only from \$150 thousand to \$200 thousand so far in the seventies, and only inflation is permitted to modify this figure before 1976. Hardly a real growth of 34% and certainly not per annum.

It is, of course, entirely within Sir Harold's rights to press for a strict interpretation of the UNESCO rules if he wishes. But surely when so many others are deeply concerned, an opinion which flies in the face of the advice of fellow scientists is worrying, and a mechanism by which a Royal Society-appointed committee can go to an international meeting with an un-representative view needs examination. And the figures should be right.

A LARGE monumental fountain, ornamented by the celebrated sculptor Carpeaux, has been erected on the Observatoire Place at Paris. It represents Europe, Asia, Africa, and America rotating the globe, which they carry on their heads, and is very effective; but in spite of M. Le Verrier's protestations, they are rotating the globe from east to west, according to the Ptolemean theory.

# international news

# Monod's answer to the Pasteur's problems

THE financial problems of the Pasteur Institute have long been clear to the French public and to workers at this famous French biological research institute. The Pasteur has been in the red for the past 15 years and has been obliged to conduct many fund-raising campaigns through the press and television, as well as seeking government aid.

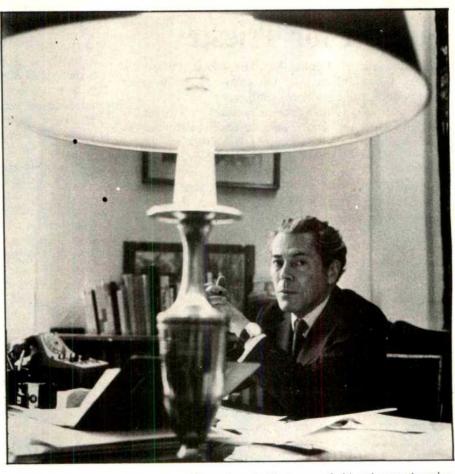

It now seems that this has not been enough to save the situation, which has been further aggravated recently in an unforeseeable way.

At a meeting on October 11, Professor Jacques Monod, director of the institute, announced to the scientific staff that there was a risk that employees and suppliers would not be paid after May 1975. Most of the assets of the Pasteur Institute have already been sold and no more credit can be obtained.

The annual amount spent by the institute will reach about 65 million francs by the end of 1974, of which various government contracts will pay for around a third. Unfortunately the institute cannot count on profits from its new factory for producing vaccines and sera, set up in Normandy in 1973. Although sales are satisfactory, production costs have risen much higher than expected. Profits are thus much lower than predicted and financial equilibrium is several years off.

Added to this gloomy financial situation is the deplorable condition of many of the buildings centred around the Rue Doctor Roux. Only the departments of molecular biology and virology occupy new or renovated buildings. The department of bacteriology is scattered over several buildings, some of which date from the time of Louis Pasteur himself. In some cases even normal security precautions cannot be enforced. In crumbling lecture theatres, students have to write on their knees. The building of a long awaited new immunology department seems to have been adjourned sine die for financial and administrative reasons.

Unless a great deal of work is started quickly, Professor Monod fears that a creeping paralysis will overcome work

Monod at the Pasteur; a bold and attractive plan.

at the institute. But in the present parlous state of the finances, even the urgent improvements cannot be started.

To disentangle the institute from this mess, Professor Monod has just presented a bold and attractive plan to the institute's Council of Administration and the public authorities. He wishes to sell all the buildings and land in the Rue Doctor Roux and rebuild the institute at an entirely new site at Garches, 10 kilometres to the southwest of Paris. Because of the enormous rise in land values in the centre of Paris, the sale would raise sufficient funds to enable the institute to build its new laboratories and still leave a profit of 70 million francs. An operation on this scale could, of course, not be realised without government approval. Also, many of the scientists, although admiring Professor Monod's effort and imagination, ask whether the project is realistic in the present uncertain economic climate in France. The fact that the financial forecasts for past years have turned out to be wide of the mark

and that details of the financial situation remain unknown to most of the workers, clearly raise doubts among the researchers about the validity of the new project. The Pasteur Institute is being asked if all possible efforts have been made to find a less grandiose but less risky solution, and it is feared that the financial and technical crisis may precipitate a crisis amongst the staff.

Whatever the final solution turns out to be, it will be a painful one for the institute and those who work there. Research teams may not survive the upheavals of the next few years and some researchers and technicians may well leave the institute.

At the end of November, the government representatives on the Administrative Council will give the government's decision and a final decision will be arrived at on December 19. In the meantime, M. Royer, the President of the Administrative Councils plans to hold a meeting with the staff in the absence of Professor Monod.

Ukrainian Medical Academies, and the Vinnitsa Procurator's Office-so far without any effective reply.

The trial was scheduled for October 30 but enquiries made by Dr Shtern's sons, Viktor and Avgust, to the Procurator's office, elicited only the information that the legal proceedings were "no business" of theirs. The only news forthcoming is that the 56-yearold doctor is in a serious state of health, with internal haemorrhage from a duodenal ulcer and tuberculosis. He is at present being held in an underground room and is to be visited by a medical commission.

It is, of course, possible that the

WITH talk of massive cutbacks in federal spending to help fight inflation, and with the 1976 budget just three months from publication, some members of the scientific community in the United States are getting the jitters. And well they might, for expenditures on science and technology fall almost totally in the so-called controllable category of the federal budget, thus making them prime targets for reduction.

One area which is clearly going to be hard pressed is high energy physics, and the Zero Gradient Synchrotron (ZGS), a proton accelerator located near Chicago, is a likely candidate for extinction. The Office of Management and Budget (OMB), which prepares the Administration's budget request, has already decided that the ZGS should soon be consigned to the technological scrap heap, for earlier this year it asked the Atomic Energy Commission and the National Science Foundation to develop a "plan for shutting down the ZGS accelerator at the earliest possible time".

The rationale for that decision is that since money for high energy physics is unlikely to grow in these

### Foot on the brake for accelerators

by Colin Norman, Washington

times of financial stringency, and with the new Fermi National Accelerator soaking up a rapidly growing proportion of funds available for that esoteric science there just is not enough money to operate all the particle accelerators at a reasonable level. The ZGS machine being the least powerful of the high energy accelerators, and also being located close to the new Fermi accelerator, looked like the logical one to shut down.

There is, of course, nothing new in such a trend. To accommodate the growing operating budget for the Fermi machine-which began work about two years ago-the Atomic Energy Commission cut off funds for the Princeton-Pennsylvania accelerator in 1971, axed the Cambridge Electron Accelerator a year later, and is now in the process of converting the Bevatron from a high energy machine into a heavy ion accelerator.

But, having decided that the ZGS should be the next to go, the office of Management and Budget must have been astonished at the advice it received on how the deed should be done. A special AEC-NSF committee which was set up to develop a plan for shutting down the ZGS, told the budget cutters in an unpublished report last month that it found whe ZGS programme to be "vigorous and innovative" and that it could see "no scientific or technical reason to recommend a shutdown at this time". Ask a silly question

The committee pointed out that some features of the ZGS are unique, and that just because it is operated at a relatively low energy does not necessarily mean that it is the most expendable of the high energy accelerators. To confuse the OMB people even further, the committee recommended that operation of the ZGS should be continued "possibly at a more intensive level" for the next four years, and that mid-1979 should be considered the earliest reasonable time to shut the machine down.

### Radical medicine in Beersheba

from Nechemia Meyers

ISRAEL'S fourth medical school, attached to the Ben-Gurion University of the Negev, opened this month in Beersheba with a first-year class of 34 students, two of them Arabs.

Was there any justification for yet another medical school in a country with the world's highest ratio of physicians to potential patients (about three per thousand) and hundreds of students at existing schools, not to speak of the 1,500 Israelis studying medicine in Europe? Many people, particularly those connected with the other three medical schools, think not. But thanks to the missionary zeal of its chief advocate, Professor Moshe Prywes, it is now an established fact.

Prywes, connected for many years with the Hebrew University Medical School in Jerusalem, is determined to develop a very different kind of institution at the Ben-Gurion University, of which he is president.

He wants to use the new school as a means of breaking down the barriers that now exist between academic medical centres on one hand, and neighbourhood clinics on the other. At present, Israel's best qualified doctors, graduates of her own medical schools, cluster around the universities hospitals, university-affiliated leaving day-to-day medical care to be dispensed mainly by old-timers and new immigrants. And the neighbourhood doctors, being effectively cut off from hospitals and research centres, tend to practice out-of-date, conveyorbelt medicine-which makes them frustrated and their patients dissatisfied.

Prwyes aims to ensure that the graduates of his school are different by training them to be patient-oriented from the outset. For example, the schools calls for students to work in clinics and hospitals, under the supervision of special tutors, from their very first year.

Internship will also be handled in a new way. Instead of becoming interns at the end of their studies, the fledgling medicos will spend a full year working in the field, albeit with limited responsibilities, midway through their course.

The Ben-Gurion University Medical School, unlike others in Israel, will play down basic biological research, emphasising instead research linked to the specific health problems of the community. While not in any way denying its importance, the directors of the new school advise would-be students who are primarily interested in research to enrol elsewhere.

This same philosophy is reflected in

the selection of members of faculty, among whom are men who have never written a scientific paper in their lives. In Prywes's opinion, physicians who have proved themselves as lecturers and as doctors in the field are as qualified to be professors as are research-oriented MDs with dozens of papers to their credit.

These unorthodox professors, it is hoped, will set an example for their students. "Hitherto," Prywes has pointed out, "neither the medical student nor the resident saw his teachers working outside the hospital or the research laboratory. Thus talking to students about the importance of community medicine was bound to be a waste of time. They could hardly be convinced of the significance of something their own mentors ignored."

### Stormy weather hits Mexican research

FLOODS and very early frosts have destroyed several years' worth of research at the International Wheat and Maize Improvement Center, the internationally renowned plant breeding institute run by Norman E. Borlaug in Mexico. Frost killed off most of the hybrid wheat and maize being bred at two research stations near Mexico City early in September, and floods associated with hurricane Fifi completely devasted a third station in eastern Mexico three weeks later.

In most cases the crops—which represented the results of two or three years of cross breeding-were destroved before they had produced seed for planting next year. According to Dr Robert Osler, deputy director of the center, there is no reserve seed from intermediate hybrids so it will be necessary to go right back to the original strains and cross breed them again over the next two or three years to reproduce the destroyed plants.

Osler said that up to 80% of the wheat and the entire maize crop was destroyed at a station at Toluca near Mexico City by frosts which arrived several weeks earlier than usual. The same frosts also wiped out most of the maize at another station on the other side of Mexico City, although much of the wheat crop there survived. Osler fears, however, that because the frost caught the plants at a relatively early stage the seeds may be difficult to germinate.

Flood damage to the third station is more serious. Torrential rain associated with hurricane Fifi-the one which devastated Honduras-caused a river to burst its banks and flood fields at a research station located at Poza Rica to a depth of 3 metres. Osler said that the water took the topsoil off a

large area and flooded silos and machinery sheds.

Osler estimated that it could take at least a year to repair the damage, one problem being that replacing the topsoil could introduce a good deal of variability in soil condition. The Center has applied to the Consultative Group, an international group of donors which supports crop breeding research, for funds to repair the damage. There is also a possibility that a European government may provide at least part of the money.

### Rhodesia rules

"THE University [of Rhodesia] has been exempted by the British Government and others from sanctions." So runs the last sentence of a sheet describing Salisbury, its university and the chair of biochemistry which was being advertised recently. What does this mean in practice? One of our readers enquired of the Foreign Office in London and got the following replies:

Can I convert European currency into Rhodesian currency? Travellers to Rhodesia are normally only permitted to take £25 in sterling notes.

What personal goods can I take? Household and personal effects, but not

Can I order and receive scientific research equipment? Export to Rhodesia is prohibited except by licence issued only for humanitarian reasons (religious, educational or medical). Each application is considered separately; present policy is to give "sympathetic consideration to applications from the University of Rhodesia"

Can I advertise in the United Kingdom for technical and administrative personnel? Only under licence (the same criteria apply as above). Present policy is to issue licences for academic but not for other posts.

Can I seek research grants in the United Kingdom? Nothing prevents you, but the transfer of funds is subject to strict exchange control ruleseach case is considered on its merits.

Can I change Rhodesian currency back into other currencies? It cannot be exchanged in the United Kingdom. "I cannot say what facilities are available in Rhodesia.'

He's not going.

We called the Foreign Office for clarification of some items and they draw attention to two points. First, nothing can be taken for granted in dealing with the United Kingdom from Rhodesia. There are no automatic exemptions and everything has to be reviewed. Second, there is no British representative in Rhodesia, so none of the customary consular facilities either of a routine or an emergency nature are available.

THE abrupt departure last week of Dr tioned its appearance on the Washing- bill to dissolve the AEC and replace it John Sawhill as head of the Federal ton landscape. Energy Administration (FEA) came as survive, and although he was generally ordinating committee which consisted regarded as an effective administrator who won praise from Congress and consumer organisations, he has trodden on a good many important toes recently.

His resignation—which can be described as forced rather than voluntary -paved the way for the appointment of Andrew E. Gibson as the new administrator of the FEA. Gibson's background is not in energy policy but in maritime affairs—he is a former Maritime Administrator and Assistant Secretary of Commerce—but that is not surprising since relevant experience has rarely been a criterion for appoint- of top officials of government agencies programme. It is that factor which has ment to a top energy job in either the carrying out energy programmes. Nixon or Ford Administrations.

Seamans, an aeronautical engineer, and development programme, and his appointment has so far been generally welcomed. He faces a tough job, however, in getting the ERDA off the ground since bureaucratic jealousies are sure to arise when programmes are shifted from existing federal agencies into the new organisation. And, since the ERDA will be built around the laboratories of the Atomic Energy Commission, he will be faced with the difficult task of striking a balance between nuclear and non-nuclear research.

The appointment of Anders has, however, drawn mixed reaction. As head of the NRC, Anders will be placed in charge of regulating nuclear power plants and ensuring that they meet safety criteria. He has been a Commissioner of the AEC for some 15 months, where his chief responsibility has been to oversee the breeder reactor drawn some sniping, since the breeder All that was changed by President reactor has become one of the chief targets of nuclear critics

Another set of statistics shows that,

# India parcels out its energy problems

from Narender Sehgal

RECENT changes in the central council of ministers, following a cabinet reshuffle, have resulted in the creation of a separate Ministry for Energy, to be headed by a minister of state (slightly lower in status than a full fledged cabinet minister). This, however, does not mean that all subjects relating to energy have been brought under one roof. Far from it; as of now, only 'power' (from the erstwhile Irrigation and Power Ministry) and 'coal' (from 'mines' which until now had been under the charge of the Ministry of Steel and Mines) have been assigned to the new ministry.

Fears are already being voiced about the administrative problems that may arise from the change. For example, much of the hydroelectric power produced (37% of the total generated in India by all means) is tied to irrigation projects, hence their association in a single ministry. (Irrigation will now form part of the Ministry of Agriculture.)

Oil, which accounts for 50% of India's entire consumption of energy derived from commercial sources, remains, as before, part of Petroleum and Chemicals under the charge of a cabinet minister.

The diversity of coal users (railways and the steel and fertiliser industries, for example) presents an additional problem of administration and coordination. It remains to be seen if it is possible to retain all matters concerning coal within the ambit of the newly created Ministry of Energy.

Then there is atomic energy which remains under the direct control of the Prime Minister. In this area of increasing importance, Shrimati Gandhi has been in the past assisted by Shri K. C. Pant who will continue in this role even after he has taken charge of the new Ministry of Energy.

On the basis of the past record of co-operation and coordination between various ministries, it is not possible to feel overly enthusiastic about this new attempt to solve India's grave and growing energy problems.

• India is known to have uranium in only small amounts. Known deposits, at present rates of production and consumption (with due allowance for planned future uses) would last no longer than some 30 years. On the other hand, China is understood to possess uranium in fair abundance in relation to her immediate and long term needs. One would think, then, that China could not possibly have any use for Indian uranium.

No so. Men arrested by the Bihar police recently, with varying quantities of uranium in their possession, have revealed that the stolen metal was meant to be smuggled to China through Nepal and that another 100 kilograms or so was awaiting disposal at various places in Bihar. An editor of the Hindi daily at Patna, engaged in investigating the smuggling operations and possessing some related documents, was reportedly murdered and relevant documents stolen by the apparently well organised gang of uranium smugglers, just before the newspaper was about to publish the story.

The uranium in question was stolen from the Jadugoda mines near Jamshedpur in Bihar. While investigations and more arrests are continuing, the view is gaining ground that the motivation behind the Chinese interest in Indian uranium may have to do with her desire to weaken or slow India's atomic energy programme.

## Weather watch down under

by John Gribbin

THE Commonwealth Meteorology Research Centre, which was set up in 1969 with a five year lease of life, has recently been reconstituted and provided with an extension for a further five years, under the auspices of the Australian government. Now the Australian Numerical Meteorology Research Centre (ANMRC), this Melbourne based operation is playing a key role in studies of the problems of meteorological research in the southern hemisphere.

These problems are formidable indeed. Because of the great proportion of ocean in the south the observational network is far from complete; in addition, the distribution of what land there is means that population in the southern hemisphere is concentrated in the tropical and near tropical regions, north of 40°S. And far less is known about the behaviour of weather systems at these latitudes than at extratropical latitudes.

During its first five years of existence under the "Commonwealth" label, the centre was closely allied with the Global Atmospheric Research Programme (GARP), and this spirit seems likely to continue. In July of this year, when the centre was renamed, the Australian government affirmed support for the next five years, with research objectives defined in the following terms:

"The work of the Centre consists of studies of the behaviour of the earth's atmosphere, with emphasis on general circulation, directed towards improvement in the accuracy and timescale of weather forecasting, and towards improvement in understanding the distribution and variations in climate on the earth."

The work at the ANMRC is, as its name suggests, strongly orientated towards computer studies, with facilities available on the IBM 360/65 at the World Meteorological Centre in Melbourne (this centre is the southern counterpart of the two WMCs in Washington and Moscow, the three forming part of the World Weather Watch). With the aid of modern satellite photography, many of the handicaps resulting from the shortage of observing stations in the south can be overcome; satellite and other data are combined in mathematical models of atmospheric flow which have already produced reasonable forecasts for one to four days ahead. Improvements are likely to come on two fronts: through introducing more representations of physical processes into the model (better 'skill'); and through refining the numerical methods used (better 'efficiency').

In global terms, the Australian work is particularly interesting because it offers an alternative mathematical approach to some of the problems which beset meteorologists attempting to produce global models. So far, such models have encountered difficulty because of problems near the poles, and although progress is being made there is a need for different approaches to resolve the difficulties. The ANMRC has been working with the so-called 'spectral method', which involves representing the atmospheric variables by a truncated series of spherical harmonics, and with a combination of spectral techniques and grid techniques, which they refer to as a 'semi-spectral' or Fourier model.

In a draft version of part of the 1974 Annual Report of the ANMRC (as yet unpublished) it is stated that "a significant proportion of the operational products [sic] now issued by the National Meteorological Analysis Centre of the Australian Bureau of Meteorology are numerically derived", although "manual intervention" is still an important part of the forecasting process. The draft goes on to say that the Fourier model is now also proving useful in basic atmospheric research, and is helping to provide an insight into the dynamics of the stratosphere and mesosphere; in future years, as the research programme matures, the ANMRC sees a greater emphasis on such problems as the influence of volcanic debris and of anomalies in sea temperatures on climatic surface 

### The language of space

from Angela Croome

Lt.-Colonel Alexeit Leonov, commander designate of the Soyuz crew for next summer's Apollo-Soyuz linkup (the ASTP) announced a nice compromise on the question of space communications during the joint presentation on ASTP progress at the Amsterdam International Astronautical Congress. Last year it was not known what the language of space would be, said Leonov; it had now been decided that on the mission the Russians would speak English and the Americans Russian. In an emergency each team would revert to its own language. It had not however been fixed who would take overall command in a crisis.

The 'book' of operational proce-

dures had been written and practised in the four joint training sessions. Emergency procedures had yet to be worked out and there was further polishing of the language to be done; this had proved much more of a problem than originally envisaged (though judging from Leonov's competent performance, his English was no longer a headache). Still to be fully sorted out was the ticklish question of the interrelation of the two control centres. There seemed no clear indication that an American team of controllers would be sitting in at Baikonur next July

Both the Russians and the Americans assured questioners that there was nothing to choose between the two sides in terms of input to the engineering and other design and operational concepts. Nonetheless behind the

scenes American space planners were saying the flow of information was all one way and in the space medicine field in particular there was a great scarcity of adequate Soviet data. How had the Soviet programme eradicated early problems with motion sickness? Skylab astronauts, groggy and sick during their first week in the orbital workshop, would dearly like to know.

### Medallurgy

We are agog to see whether our hint (Nature, 246, 113; 1973) that the Royal Society's policy for the distribution of medals was just a trifle inward-looking has fallen on fertile ground. It's medalstime again next week and several Fellows have told us they will try and persuade Council to look further afield this year.

# correspondence

### Radioactivity salted away

SIR-Referring to the article "Fruits of a Faustian bargain" (Nature, 251, 274; 1974) it appears that the United States propose tests in 1980 for the storing of radioactive waste so as to stop dumping it—as do the UK, USSR and other nations—in the ocean. The German authorities seem to be ahead of them, as for several years now, low and moderately radioactive waste has been stored in a salt mine close to Hannover by the Gesellschaft für Strahlen-und Umweltforschung owned by the Federal German Republic. And there is still space for thousands of barrels for decades to come. It may be taken for granted that no earthquake will occur to wreak havoc-for millions of years none has happened there. so the only thing to fear is mankind itself by trying to prove its efficiency by discovering a new and final way of self destruction.

HANS K. KOENBER

Laser & Electro-optik, D-8000 München

### Plasmid moratorium

SIR—The appeal by a committee of eminent biomedical scientists for a voluntary moratorium on an area of scientific research which may create unpredictable hazards to human health (Nature, 250, 175; 1974) reminded me of a talk which Leo Szilard gave at a writers' club in Moscow in December 1960 which I attended, and where to my knowledge the question of a moratorium was raised for the first time. This story was later told by Szilard

and published1.

"A year ago last December I was in Moscow to attend the sixth Pugwash conference. And while I was there I was invited to talk to a writers' club about molecular biology, about my work. One of these writers said, 'Now what practical consequences does this have?' So I said, 'As far as I can see it has no practical utility whatever—but of course if you had asked me that about nuclear physics in the 1930s I would have told you the same thing.' And then the Russian said, 'Well in that case, wouldn't it be better if you stopped right now?'".

Yours faithfully, Gertrud Weiss Szilard

La Jolla, California 92037 <sup>1</sup> Thinking Ahead with Leo Szilard, in Int. Sci. Tech., 33–38 (1962).

### Sitting Bull?

SIR-I was startled to read (Nature, 251, xviii; 1974) that Colorado State University is encouraging 'ethnic minorities and women" to apply for the position of Chairperson in its Statistics Department. I reject as highly improbable the implicit assumption that ethnic minorities necessarily consist entirely of males. Nevertheless, I wonder whether the aim is to encourage collective applications resulting in large-scale migrations of American Indians (that is deviations from their normal distribution). Does this mean that sophisticated statistical tests (excluding Student's t, of course) will then be used to select individual chairpeople

from large samples? And, even if this analysis is at variance with the real object of the exercise, won't the unsuccessful applicants sioux?

Yours faithfully.

F. A. SMITH

Department of Botany, University of Adelaide, Adelaide, South Australia 5001

### ILLL reactor?

SIR,—Although apposite and allusive alliterations are always amusing and appropriate as acronyms, Institut Laue-Langevin still satisfies many of us. It recalls that the construction of this long awaited reactor is owed to a Franco-German agreement, whilst with 1,000 visitors and 300 completed experiments in the last year, the Institut is already known as ILL the world over.

I believe we should 'let ILL alone'.
Yours faithfully,

W. M. LOMER

Institut Laue-Langevin, Grenoble, France

### Erratum

SIR In my news note (Nature, August 9) credit for the fallopian tube transplant experiments in animals should have gone to Dr B. M. Cohen of the University of Cape Town Medical School, not to his close colleague Dr M. Katz, who has drawn my attention to the error. I apologise to both gentlemen.

IAN RIDPATH

# How to have your fibrous cake and eat it

FIBRE reinforced plastic composites combine the high strength and modulus of strong fibres with a high work of fracture (toughness). Two letters in this issue describe methods of improving the work of fracture without significantly reducing the strength.

A high work of fracture allows one to use a material secure in the knowledge that in a structure it will show signs of failure long before it actually breaks. It might be thought that the combination of brittle fibres with a brittle resin would produce a brittle composite. The toughness of these materials is the result of energy-absorbing processes at the weak fibre-resin interface during fracture. The most important of these processes is probably the work of pulling out broken fibres after the crack tip has passed, leaving a whiskery fracture surface. This work decreases as the interfacial bond strength is increased because the crack then cuts more cleanly through the fibres leaving shorter pull-outs. On the other hand, to weaken the bond strength also weakens the composite.

A new approach demonstrated by Atkins (page 116) is to produce alternating strong and weak bonded regions on the fibres. The strong zones maintain the composite strength, the weak regions allow lengths of fibres to debond, break and pull out so toughening the material. He uses boron fibre-epoxy resin composites with bands of silicone grease or polyurethane varnish on the fibres to produce weak bonding while, he claims, the uncoated regions will be strongly bonded. The varnish-coated composite shows a remarkable increase in toughness at coating levels above 50% and the strength is maintained up to 90% coating. For the silicone grease the toughness increase is much more modest. The results all fit Atkins's analyses for strength and toughness. The increase in toughness with varnish coating

is from 50 kJ m $^{-2}$  with no coating to 200 kJ m $^{-2}$  at 90% coating with no strength loss. Conventional surface treatments would only be expected to produce variations of a few per cent about the lower value without also changing the strength.

What is not clear yet is whether the varnish and grease both do act as weak coatings relative to uncoated fibres. The difference in the results for the two coatings suggests that the full explanation is more complicated. The system is obviously of commercial interest but also could be scientifically productive since our knowledge of this interface (like that of most interfaces between different phases or materials) is very limited. Carbon fibre reinforced plastics may be expected to show similar improvements but it is interesting to note that the silane treatments used on glass fibres are known often to form beads on the glass surface rather than smooth coatings.

A second approach to toughening is described by Gordon and Jeronimidis (page 116), who have considered the arrangement of cellulose fibrillae in the cell walls of timber. Gordon has remarked before that trees seem to have opted for a high work of fracture rather than maximum strength or modulus. Reasoning that this might be associated with the helical arrangement of the fibrils around the cell wall, Gordon and Jeronimidis now show that under stress the helical tube collapses and the structure undergoes extensive deformation before breaking. They report that model composites constructed on the same basis show very high work of fracture values (400 kJ m<sup>-2</sup>). They report no strength or modulus measurements but theoretically the decrease in modulus should be small and presumably strength will behave similarly.

Many other approaches to improving the low toughness of boron and carbon fibre reinforced composites are also being studied. But there is a long way to go before materials of the complexity of bone, ligament or timber are developed and before the material is designed concurrently with the structure in which it will be used.

### Micrometeoroid density from lunar craters

THE Solar System not only contains planets, moons, asteroids, comets, meteorites and meteorids but also a plethora of smaller particles known as micrometeoroids. These are so small that they do not burn out when they enter the Earth's atmosphere but are gently retarded by momentum transfer to the air molecules and slowly float to the ground. All particles with masses less than 10-6g fall into this category, the Earth's surface collecting 3,000 tonnes of this material each year, enough to form a layer of dust 1 cm deep during the Earth's lifetime. The physical properties of these particles can only be measured indirectly. Experiments flown on satellites and space probes measure mass, velocity and sometimes orbit. Rockets can be used to collect the particles in the atmosphere but only pick up the micrometeoroids after they have been retarded by the atmosphere and contaminated by meteoric dust ablated from larger meteoroids. Studies of zodiacal light lead to values for the particles' dielectric constant and shape.

A new and exciting way of studying the properties of micrometeoroids is by investigating the surfaces of the small glassy spherules found in the samples of lunar soil returned to Earth by the Apollo and Luna space programmes. These spherules are formed like raindrops during the solidification of the molten ejecta blown out from the lunar surface during impact cratering and volcanic events. They then lie on the surface, exposed to space and to the micrometeoroid influx. As the Moon has no retarding atmosphere the micrometeoroids strike the spherules at velocities between 5 and 20 km s<sup>-1</sup> and produce small craters.

Spherules have around 5,000 microcraters (diameters a few  $\mu$ m) per square centimetre of their exposed surface, the numbers of craters increasing with decreasing crater diameter. A typical microcrater is shown in Fig. 1.

Smith, Adams and Khan have concluded—in a communication on page 101 of this issue of *Nature*—that by comparing the ratio of crater depth to diameter in microcraters on the surface of lunar spherules with this ratio for laboratory-produced impact craters in glasses they can estimate the densities of micrometeoroids, the percent-

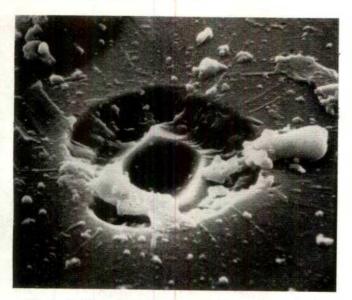

Fig. 1 A 13 µm impact crater on a lunar glass spherule. The spall zone has removed the raised rim and contains radial and concentric fracture patterns (NASA S-71-45362: courtesy of Friedrich Hörz).

ages of the micrometeoroid influx having differing densities and the way this percentage varies with particle mass. They find that the microcraters fall into three distinct groups having depth to diameter ratios of 0.94 (deep craters), 0.50 and 0.33 (shallow craters). By measuring craters produced by impacting hypervelocity (~3 km s<sup>-1</sup>) iron, aluminium and polystyrene pellets on to soda lime glass, tektite glass and quartz the authors conclude that the ratio of crater depth to diameter decreases when the projectile density decreases and that the three different ratio values found for lunar microcraters are produced by iron micrometeoroids (density 7.9 g cm<sup>-3</sup>) stones and carbonaceous chondrite micrometeoroids (density 2.7 g cm-3) and low density (1.2 g cm<sup>-3</sup>) particles, possibly spongy micrometeoroids or even ice crystals. The perentages of high, medium and low density particles in the  $\sim 2 \mu m$  diameter range are 40, 20 and 40% respectively. Measurements were also made in the laboratory of the ratio between the crater diameter and the diameter of the incident particle. The authors find that iron particles produce craters of twice their own diameter, the spongy micrometeoroids producing craters having the same diameter as the projectile-so the mass of the projectile responsible for a crater can now be calculated easily. Considering particles with diameters greater than 2 µm the incident mass is found to be made up of 20% iron micrometeoroids, 10% stony micrometeoroids and 70% spongy micrometeoroids. So spongy micrometeoroids which for a long time have been thought to be the predominant type in the radio meteor range of the mass spectrum (that is, >10<sup>-6</sup> g), also predominate down to about 10-10 g, a result which indicates that some differentiation process must have occurred during the production of these small particles.

Many events have been suggested to explain the origin of micrometeoroids—among them being debris from asteroidal collisions, condensations in the outer solar corona, accretion and condensation of interstellar material, remnants of the primordial dust cloud that produced the planets and debris from decaying comets. This new result should help to narrow the choice. It can be compared with observations of meteorites, the large bodies (>10° g) which penetrate the atmosphere and can be subsequently collected and analysed. Here irons make up 6% by number, stones and stony irons 94%. So these two types of particle of very different size have entirely different relative proportions of irons and stones.

Smith, Adams and Khan also find that the nature of

micrometeoritic material depends strongly on the region of the mass spectrum being considered, the proportion of iron particles increasing as particle size decreases. The region with particle diameters between 1 and 2 µm (mass ~4×10<sup>-12</sup>g) is found to be a region of transition, larger particles having predominantly low densities, smaller particles having predominantly high densities. This is another very important result because it could be the first definite observation of the effect of radiation pressure on the micrometeoroid dust cloud. In the Solar System the force due to radiation pressure opposes that due to solar gravitational attraction and the two forces cancel out for spherical particles at 1 AU when the product of the particle diameter and density equals 1.2×10-4 g cm-2. For particles of densities of 7 and 1 g cm<sup>-3</sup> the limiting diameters are 0.2 and 1 µm respectively, smaller particles being quickly blown out of the solar system. 1 µm should then be the 'cut off' size for low density particles and this is exactly what Smith, Adams and Khan have found. For smaller particles to have stable orbits they must have high densities. Assuming that 7.9 g cm<sup>-3</sup> is the highest particle density an extrapolation of the authors' results indicates that no particles of mass less than 10-14 g can come within 1 AU of the Sun and have a stable orbit. So the increase in particle numbers with decreasing mass should halt at 10-14 g. Smaller particles than this should be very rare, the few present having been produced in the recent past and moving in hyperbolic orbits as they escape from the Solar System. But this prediction is difficult to check because 10-14 g is right at the limit of detection for satellite, space probe and lunar cratering experiments.

DAVID W. HUGHES

# The linear differentiation of chromosomes

From the first description of an induced differential staining of plant chromosomes following cold treatment (Darlington and La Cour, J. Genet., 40, 185; 1940) twenty-eight years were to elapse before Caspersson and his colleagues (Expl Cell Res., 49, 219; 1968) showed that chromosomes treated with quinacrine mustard displayed a series of lateral fluorescent bands. This technique became known as Q banding and was quickly followed in other laboratories by the development of the C, G, R, G<sub>II</sub>, T, N and Cd banding and the DNA/RNA hybridisation in situ techniques. These techniques have had great value in the recognition of individual chromosomes and the analysis of translocations and other rearrangements-since extended to all hybrids, especially man-rodent hybrids. They have introduced to human cytogenetics refinements comparable with the contribution of the salivary gland chromosomes to Drosophila cytogenetics. In addition, they have stimulated speculation about the biophysical and biochemical organisation of chromosomes which this article attempts to review.

Discovery of the causes of C, G and Q banding should illuminate the long-standing distinction between constitutive heterochromatin and euchromatin, now found to be repetitive and unique DNA sequences respectively. Most methods involve treatment of acetic/alcohol fixed chromosome spreads in solutions of varying pH, temperature, and ionic strength followed by staining with Giemsa or fluorescent dyes, though the age and quality of preparation are found to be of great importance. The principles are often more important than the actual recipe and the successful outcome is so variable that the methods have been compared to Chinese cooking (Mammalian Chromosome News Letter, 15, No. 2; 1974).

Histone distribution, AT/GC base ratio and denaturation

### Maintaining genetic diversity

Among the many recommendations of the United Nations Conference on the Human Environment (Stockholm, 1972) which are beginning to bear fruit are those on the conservation of genetic resources. Registration of bacterial culture collections and seed banks is already under way. Now an *Index of Living Plant Collections in the British Isles* has been compiled by Dr J. T. Williams (Bentham-Moxon Trust, Royal Botanic Gardens, Kew, 1974). In his introduction to the index Professor Heslop-Harrison says that "the compilation of the present index was not inspired directly by the UN recommendations [having been started before the Stockholm conference] but its intent is wholly consonant with them".

This preliminary index lists institutions with collections of higher plants and collections actively being used in research. It is being distributed worldwide by the International Union for Conservation of Nature and Natural Resources; possibly also by the Food and Agriculture Organisation of the United Nations, as a step towards the ultimate aim of an international register of living plant collections.

of DNA were each proposed as possible causes of Q, G and C banding patterns. Histones however were shown to be partially extracted by fixation and even when they were completely removed by HCl post-treatment G banding was not affected (Comings and Avelino, Expl Cell Res., 86, 202; 1974). Similarly, we have observed (Ockey, Nobel Symp., 23, 344; 1972) that removal of histone labelled with tritiated precursors is uncorrelated either negatively or positively with G or C banding. Since proteolytic enzymes alone induce G banding and fixation does not seriously denature DNA, differential denaturation was also ruled out as the main cause of Q and G banding. But C banding requires alkali treatment which does induce denaturation with a subsequent rapid renaturation of the highly repetitive DNA sequences in the SSC stage of treatment. Other factors are however involved. Comings and his colleagues (Expl Cell. Res., 77, 469; 1973) and Pathak and Arrighi (Cytogenet. Cell Genet., 12, 414; 1973) both showed that DNA is lost preferentially from the non-C band regions; this may therefore explain their subsequent Giemsa differentiation but by quantitative autoradiography we have observed (unpublished) that when older <sup>3</sup>H-thymidine labelled preparations are used C bands are visible in many chromosomes that show equal loss of DNA from C and non-C band regions.

The C-banding technique is related to the earlier technique of DNA/RNA hybridisation in situ (Pardue and Gall, Science, 168, 1356; 1970) using RNA transcribed from satellite DNA. Both involve the denaturation of DNA and both are supposed to locate constitutive heterochromatin yet there may still be some discrepancies between them. The human Y chromosome has always shown up as constitutive heterochromatin in C banding but until now had given no indication of repetitive DNA by the hybridisation method. Recently, however, Evans and his

colleagues (Nature, 251, 346; 1974) showed that the Y contained repetitive sequences of all the four AT-rich satellites so far fractionated from human DNA. Constitutive heterochromatin was originally regarded as being ATrich, presumably because satellite DNA was AT-rich but this has been found not to be the rule. Other results have indicated that constitutive heterochromatin regions may react differently to different techniques. Some C-banding sites are non-fluorescent with quinacrine as in the human karyotype, but the Y chromosome, which also contains C band repetitive sequences, is the most fluorescent chromosome of the complement. Hoechst 33258, a more recent fluorescent dye, stains the ATrich C bands in the mouse but not O bands while in Microtus both typical O and C bands are stained (Hilwig and Gropp, Expl Cell Res., 75, 122; 1972). Facultative heterochromatin (that of the inactive human X which is represented by the late replicating sexchromatin body in interphase) behaves like the active X with all known banding techniques, whereas most of the other forms of late replicating heterochromatin can be differentiated by Q and G banding.

It has been proposed that because guanine quenches fluorescence, Q bands must be AT-rich, but this has proved a false trail. Recent work, both with synthetic DNA polymers and with AT-rich satellite DNAs would suggest that the important considerations for quinacrine fluorescence were the sequential arrangement of base pairs, particularly the periodicity of guanine residues which show localised quenching of AT-rich regions, and the availability of binding sites (Selander and de la Chapelle, Nature new Biol., 245, 240; 1973; Weisblum, Nature, 246, 150; 1973). The recent synthetic polymer studies with Hoechst 33258 by Weisblum and Haenssler (Chromosoma, 46, 255; 1974) show that fluorescence of this compound is enhanced by both AT- and GC-rich DNA, enhancement being greater however with AT-rich DNA.

Gottesfeld and his colleagues (Biochemistry, 13, 2937; 1974) have carried these studies a stage further with detailed biophysical study separated euchromatin and heterochromatin, and found that quinacrine fluorescence was quenched more with euchromatin than with heterochromatin. The DNA extracted from these fractions however showed similar AT/ GC base ratios and a similar fluorescence. They suggest from circular dichroism spectroscopy studies that heterochromatin DNA probably exists in the B configuration while euchromatin shows the C form. It is interesting to note in this connection that the conformation of AT-rich DNA in bacteria varies very much in its configuration with relative humidity and over a narrow range of ionic strength of NaCl (Bram and Tougard, Nature new Biol., 239, 128; 1972), both of which are critical factors in banding.

The incorporation of base analogues into DNA also affects the staining behaviour of chromosomes. Zakharov and his colleagues (Chromosoma, 44, 343; 1974) have found a considerable reduction in chromosome spiralisation at metaphase in regions which incorporate bromodeoxyuridine (BrdU) and BrdC during the latter period of the S phase when heterochromatin is replicating. differential spiralisation No such was observed when the analogue was incorporated into the early replicating euchromatin, implying a difference in conformation of the DNA between the two forms of chromatin as suggested by Gottesfeld and his group.

Latt (Science, 185, 74; 1974) showed that BrdU, incorporated semiconservatively over two cell cycles, resulted in one of the chromatids showing strong fluorescence (monofilial incorporation), the other (bifilial incorporation) weak fluorescence using the dye Hoechst 33258. Latt explained this difference as a quenching in the bifilial chromatid with less or no quenching in the monofilial BrdU chromatid. This technique provides a valuable tool in analysis of sister-chromatid exchanges (Kato, Nature, 251, 70; 1974). Perry and Wolff (Nature, 251, 156; 1974) were able to obtain a permanent differential staining of chromatids following SSC treatment after BrdU incorporation and subsequent Giemsa staining. The bifilial chromatid was less intensely stained and less condensed that its sister. These results they suggest are probably due to a difference in protein binding to BrdU-containing DNA. They also obtained differential fluorescence with acridine orange in the two chromatids.

Bobrow and Gross (Nature, 251, 77;

1974) have found that in mousehuman hybrid cells the contrasting  $G_{11}$ banding behaviour of the parental chromosomes is retained in the hybrid. This will prove not only a valuable asset in karyotype analysis of hybrid cells but also indicates that whatever characteristic of the DNA is responsible for its Gu banding response persists even in a hybrid nucleoplasm. Others have approached this problem by studying the structure of the Giemsa molecule involved in staining. Sumner and Evans (Expl Cell Res., 81, 236; 1973) suggest that the structures of the Giemsa and quinacrine molecules are such that they are able to bridge longitudinally separated sites on the chromosome which have been brought into close proximity by folding of the DNA, and that the spatial arrangement of these sites is influenced by the nonhistone proteins. The various banding techniques would then affect the cohesion or the biochemical nature of the non-histone binding. Studies using stains whose chemical specificity is known indicate the possibility of a differential distribution of -SH and -SS- groups in the bands (Sumner, Expl Cell Res., 83, 438; 1974) or that free NH2 groups are the binding sites for banding with fluorescent dyes like dansyl chloride (Utakoji and Matsukuma, Expl. Cell. Res., 87, 111; 1974).

R, G<sub>11</sub>, T, N and C<sub>4</sub> banding may all prove equally relevant to an analysis of the biochemistry and biophysics of chromosomes, but their contribution to date is at a much earlier stage. Progress in understanding the longer established techniques has been slow, partly because few biochemists worked with the cytologists who had made the great technical advances. The many current attempts to explain banding reflect our lack of knowledge of how I cm of DNA can be packed with protein into a 1 mm transverse band. But the challenge has now been accepted by the biochemists and the results should soon be fruitful.

# Retiring Crab and gamma-ray bursts

from Andrew Fabian and James Pringle
An informal symposium held at the Institute of Astronomy, Cambridge on October 18 brought together observers and theorists to discuss two separate topics—the Crab Nebula and cosmic γ-ray bursts. Renewed interest is being shown in the Crab Nebula, the remnant of the 1054 AD supernova, because a series of occultations of the nebula by the Moon has just begun. These give experimenters a further opportunity to measure its size and structure. Ten

years ago the Naval Research Laboratory group observed the rate at which the 1-10 keV X-ray flux decreased as the Moon covered the nebula and were thus able to deduce a size of 110±25 arc minutes. Now it should be possible to obtain more accurate results, and at a variety of wavelengths.

Professor Walter Lewin (Massachusetts Institute of Technology) gave a report of his August 13 balloon observations made in northern Canada. The observation was made in the 20-50 keV range and, thanks to the accuracy of the occultation prediction, both the disappearance and reappearance of the nebula were observed. The initial indications are that the emitting region is asymmetrical (approximately 30 by 60 arc seconds with the long axis running NE-SW) and is displaced slightly to the NW of the central pulsar. There seems to be no evidence for a change of size at different photon energies.

Dr Peter Davison (University College, London) discussed two occultations viewed from the Copernicus satellite. The occultation paths, predicted by Dr Leslie Morrison (Royal Greenwich Observatory), are sweeping further south each month, and Copernicus was able to pass through the occultation shadow twice on October 7. In the MIT occultation, the difference in position angle of the Moon's limb on disappearance and reappearance was about 104°, giving two almost orthogonal scans, whereas for Copernicus the difference was 135°, preventing an easy study of asymmetry. The four measurements, this time in the 2.5-7.5 keV band, indicate a size of about 60-70 arc seconds. There is no evidence for the 2.5-7.5 keV emission being centred away from the pulsar position.

At least two more balloon flights and two rocket flights are to be launched and it is hoped that these, with their larger detecting areas, will be able to find details in the structure of the nebula and possibly an unpulsed flux from the pulsar itself.

Dr Jim Felten (Universities of Arizona and Cambridge) and Dr Bian Burn (Universities of Sydney and Cambridge) discussed the theoretical implications of occultation data. It is generally expected that the size of the nebula should decrease at higher photon energies. This is because the length of time for which an electron radiates by the synchrotron process at a given frequency varies inversely with that frequency. Thus if all the emitting electrons are accelerated in the neighbourhood of the central pulsar, only the less energetic ones, radiating at lower frequencies, can retain their energy long enough to stray far into the nebula: some theories predict the X-ray size to be 15 arc s, clearly at variance with the observations. The distribution of X-ray

emission across the nebula should also help to indicate the size of the region in which electron acceleration takes place. To complete the morning, Dr Jacob Shaham (Hebrew University, Jerusalem and University of Cambridge) discussed the possibility of steady X-ray emission from the pulsar itself produced by the release of elastic strain energy created by the slowing down of the pulsar's spin rate.

The afternoon session was devoted to a discussion of cosmic y-ray bursts. Dr Rodney Hillier (University of Bristol) gave a brief resume of the observations so far and Dr Arthur Bewick (Imperial College, London) reported on a possible detection of another event, made from a balloonborne detector on September 27. The original discovery of the bursts was made by the Vela satellites each of which contains a small omnidirectional γ-ray detector for the purpose of detecting y rays from nuclear explosions on Earth. The relative times at which each satellite is triggered can then be used to compute the position of the y-ray source. Serendipity again came to the aid of science when it was found that the positions of the sources of some bursts of y rays were not compatible with a terrestrial origin. Other satellites soon verified this conclusion. The total energy received in each burst is about 10<sup>-4</sup> erg cm<sup>-2</sup> and the bulk of the energy is in photons of 150 keV. although the exact shape of the spectrum is uncertain. Each burst lasts for a second or so and is often followed by another burst about 5 seconds later. Structure is evident in the data on shorter time scales as well.

The talks on observations were followed by a discussion by Professor Martin Rees (University of Cambridge) of the theoretical interpretation of these observations. Because of the relative lack of data, theorists have yielded to temptation and have had a field day constructing models to produce cosmic γ-ray burst's. There is now almost one theory for each of the twenty or so bursts seen. The power needed to produce each burst is 1033 d2 ergs, where d is the distance to the source in parsecs. Since there is as yet no clear evidence for anisotropy of the directions from which the bursts originate, it is usually assumed that their origin is either extragalactic or close by in our own Galaxy. Ideas for extragalactic sources include the early stages of radio outbursts in quasars and the outgoing shock wave produced by the explosion of a supernova. Most exponents of the theories involving nearby favour neutron stars to produce the energy needed and the short timescale: other suggestions involve scaled up solar flares, possibly from highly magnetic stars, relativistic interstellar grains

and exploding mini black holes.

Old neutron stars are thought to be quite common in the Galaxy and there are two basic means of extracting the required energy from them. First, intermittent accretion either of matter from a companion star or of comet-like bodies could explain the observed bursts. Second, starquakes can release a large amount of energy in a millisecond or so, which can be converted to y rays either by exciting particles in the star's magnetosphere or, possibly, by dissipation of seismic waves at the stellar surface. In the latter case, it was suggested that observation of nuclear lines from surface nuclei is a possibility. Future observations of these fascinating events should provide a testing ground for this plethora of theories, and should in any case (one hopes) reduce the theory-to-event ratio.

# Vertebrate palaeontology and morphology

from Barry Cox

MUCH current work in vértebrate palaeontology proceeds hand in hand with continuing investigations into the life and growth of living vertebrates, to the benefit of workers in both fields. This is the reason for the continuing success of the annual symposia on Vertebrate Palaeontology and Comparative Anatomy, the 22nd of which was held at the University of Manchester on September 24–26.

The Devonian Gogo Formation of Australia continues to produce a wealth of information, not only because it provides a new early fish fauna, but also because the specimens can be completely freed of matrix to produce undistorted three-dimensional skulls. For example, the Gogo lungfish skulls shown by R. S. Miles (British Museum, Natural History) show clearly the presence of a supraotic cavity similar to that which in living lungfish and amphibians contains an extensive endolymphatic system. Similarly, the Gogo actinopterygian skulls shown by B. G. Gardiner (Queen Elizabeth College, London) provide new evidence that the myodome evolved within that group.

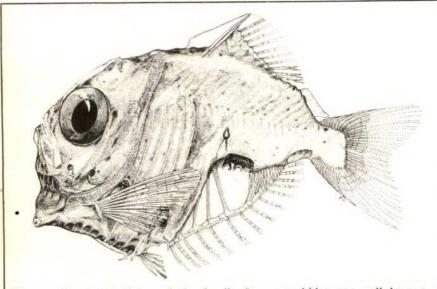

Better understanding of actinopterygian evolution, together with newer methods of phyletic investigation, are bringing more and more order to the taxonomy of the group. What had previously seemed to be taxonomically significant characters are now seen to be primitive, superficial or misinterpreted. C. Patterson (British Museum, Natural History) showed how such misunderstandings had led to the ichthyodectiform fish being placed in a

variety of other taxa, whereas they are now seen to be an independent early teleost lineage. He also pointed out that, in the case of fossil representatives of living groups, it is difficult to use a classificatory scheme to express both their phyletic relationship and their degree of morphological similarity. Patterson suggested that these difficulties could be averted by regarding each monophyletic lineage (irrespective of its rank) as a 'plesion'. These plesions would then merely be listed in a sequence, the order of which would indicate the relative morphological simlarity of each to the living sister group.

New material was also described by P. Wellnhofer (Bavarian State Museum, Munich). The fifth specimen of Archaeopteryx, though the smallest and apparently juvenile, has the most complete skull; this shows features suggesting that it was kinetic. The accepted view that it is impossible to distinguish convergent evolution in bird osteology was found by C. J. O. Harrison (British Museum, Natural History, Tring) to be unfounded—somewhat to his own surprise.

Two well known morphological/ taxonomic features received attention. The function of the hooked fifth metatarsal of lizards was explained by P. L. Robinson (University College, London). Because their proximal tarsals are functionally united with the tibia and fibula, a lever-arm for the gastrocnemius muscle cannot be formed from the calcaneum (as in mammals), but is instead provided by a tubercle on the fifth metatarsal. This fifth digit can also be rotated outwards to provide lateral stability for the foot. A new approach to the old puzzle of the differing composition of the anterior wall of the braincase in Monotremes and in other mammals was suggested by R. Presley (University College, Cardiff). who showed embryological evidence that in the latter this area may be of composite origin, including elements of both epipterygaid and prootic.

Several contributions involved biogeographical data. P. J. Miller (University of Bristol) suggested that the existence of freshwater derivatives of the marine gobies in such river systems as the Po and Arno might have been because the partial drying up, and resulting hypersalinity, of the Mediterranean during the Miocene put a premium on such evolutionary escape strategies. G. L. Underwood (City of London Polytechnic) explained how analysis of various features of the genera of natricine snakes correlated well with their distribution, spreading out from Asia through the islands of the south-west Pacific. C. B. Cox (King's College, London) showed that it was possible to define a series of

The marine hatchetfishes of the family Sternoptychidae are well known, if mainly for their rather bizarre body form and the generous development of light organs. Three genera are recognised, containing the 25 or so known species, of which Sternoptyx diaphana (illustrated) is one of the most widely distributed. Despite several studies of their biology and life style the relationships of the hatchetfishes were not well understood until a recent study by Stanley H. Weitzman (Bulletin of the American Museum of Natural History, 153 (3), 331–473; 1974) clarified their placement considerably. By detailed osteological study of several species in each hatchetfish genus as well as of their nearest relatives, Weitzmann demonstrates that they are closest to the gonostomatids. With that family, they form one of the major groups of the stomiatoid fishes. Weitzman's rearrangement of the hatchetfishes and their allies is the first to be based on osteological study of adequate material and represents a major advance in the classification of these fishes.

different patterns of faunal regions during the Mesozoic, and that these correlated well with current ideas of the varying patterns of sea barriers due partly to continental drift and partly to marine transgressions.

An elegant synthesis of electromyographic recording and of X-ray ciné film was used by K. Hiiemae (Guy's Hospital Medical School) to analyse the interrelationships between jaw movement and muscle contraction in the opossum.

## When particles hit nuclei

from D. J. Miller

How are excited states transmitted through nuclei? For some years it has been clear that we do not know the answer to this question. Surprising results were seen first in coherent production processes, where a beam particle is excited into a low-mass cluster of fast particles, without exciting or breaking the nuclear target. It seems that the fast cluster as a whole has just the same chance of interacting again, on its way out of the nucleus where it is produced, as would a single particle. This applies to clusters of two, three or five fast particles, produced by beams of gamma rays, mesons or nucleons on nuclear targets from deuterium to

Recent results from the Fermilab (Fermi National Accelerator Laboratory) near Chicago have extended our knowledge of these effects, though there is still no clear explanation. A topical meeting on high energy collisions involving nuclei was held in September at the International Centre for Theoretical Physics in Trieste. New results were reported on a whole range of related topics, including data on the multiplicity of secondary particles in particle-nucleus collisions. Nuclear emulsion workers have shown that the multiplicity of fast charged tracks produced in 200 GeV proton-nucleus collisions is only a modest factor larger than the multiplicity in proton-proton collisions at the same energy. For the mixture of nuclei in photographic emulsion, including a significant amount of bromine and silver, the factor is 1.7, and it has this value from about 70 GeV all the way up to 400 GeV. Busza's group at the Massachusetts Institute of Technology, with a simple Cerenkov counter experiment at Fermilab, has shown that the multiplicity of fast charged particles increases slowly with the atomic mass number A of the nuclide in the target, though the multiplicity in the very forward direction, within 3.5° of the beam direction, is independent of A. These experiments are 'inclusive'; they study

all final states, including the vast majority where the target nucleus has been broken up, in contrast to the unbroken nucleus involved in coherent production.

Tentative theoretical explanations by Gottfried (Phys. Rev. Lett., 32, 957; 1974), Goldhaber (Phys. Rev. Lett., 33, 47; 1974) and others have stressed the importance of the 'time dilation' effect of special relativity in understanding the passage of an excited lump of matter through a nucleus. At 200 GeV it takes about 10<sup>-23</sup> seconds for a particle to get out of a nucleus. But it may take ten times as long for a fast cluster of strongly interacting particles to get out of range of their mutual interaction. The coherent-production data show that the fast cluster behaves like one particle while it is still within the mutual interaction range. The data on inclusive multiplicities seem to be saying the same thing but with the added inference that the decay properties of the cluster are not modified by multiple collisions in nuclear matter. The results so far are fascinating, but there is scope for many more detailed measurements to be made. These could give a new source of evidence on the basic mechanisms of particle scattering, and on the structure of the particles.

# Changing views of mantle viscosity

from Peter J. Smith

THE question of the Earth's internal viscosity first became prominent in connection with vertical movements of the crust, in particular with the process of isostatic readjustment. More recently, however, the problem has assumed a much greater significance because of the important part that mantle flow processes are thought to play in the large-scale horizontal motions of continental drift and seafloor spreading. The need to find a mechanism for such motions revived the popularity of the concept of the Earth as rigid lithosphere, viscous asthenosphere, rather more viscous mesosphere and fluid core (as opposed to the equally valid, but apparently less appropriate, division into crust, mantle and core). This emphasis on viscosity then led to much closer examination of the flow properties of the asthenosphere (particularly) and mesosphere, although there is still wide disagreement over the numerical values of viscosity.

In the early studies of isostatic recovery carried out by Haskell (Am. J. Sci., 33, 22; 1937), Vening Meinesz (Proc. Kon. Ned. Akad. Wetensch., 40, 654; 1937) and others with reference to the uplift of Fennoscandia, it was assumed that the mantle flows as a

Newtonian fluid and has a uniform viscosity. This work led to the conclusion that, for an infinitely deep medium, the relaxation time (the time taken for the deviation from isostatic equilibrium to decrease to 1/e of its initial value) is proportional to viscosity but inversely proportional to the linear dimension of the removed load. Unfortunately, when Crittenden geophys. Res., 68, 5517; 1963) came to analyse the uplift of Lake Bonneville, he found that the linear dimension differed from that of Fennoscandia by a factor of about 10 but that the relaxation times for the two areas were comparable. By this time, Takeuchi (J. geophys. Res., 68, 2357; 1963) had already offered a possible explanation of the discrepancy in his suggestion that flow may be concentrated in a thin layer in the upper mantle, basing his argument on the prior conclusion by Jeffreys (Geophys. J., 8, 196; 1952) that such layered flow would involve a quite different relationship between relaxation time and linear dimension. But this was not entirely satisfactory insofar as the isostatic processes in Lake Bonneville and Fennoscandia were only reconciled by the ad hoc assumption that the flow layers beneath the two areas differ in thickness.

As a result, McConnell (J. geophys. Res., 73, 7089; 1968) decided that the assumption of uniform viscosity must be discarded, and proposed instead a mantle model comprising layers of different viscosity, generally increasing with depth. In the mean time, Gordon (J. geophys. Res., 70, 2413; 1965) had obtained a broadly similar variation of viscosity with depth by considering flow in the mantle to be due to diffusion creep (Herring-Nabarro creep). Both models led to lower mantle viscosities comparable to the 1078 poise obtained by Macdonald (Space Sci. Rev., 2, 273; 1963) from his analysis of the response of the Earth's shape to the decrease in rotational velocity. Moreover, neither model gave any cause to suppose that the assumption of Newtonian flow need be rejected; on the contrary, in Gordon's model, Newtonian flow was apparently required by the fact that for diffusion creep, stress is proportional to strain (at least for small strains).

But this consistency and agreement was soon questioned by Weertman (Rev. Geophys. Space Phys.. 8, 145; 1970) who concluded that whereas diffusion creep dominates at very low stresses (lower than about 10<sup>-2</sup> bar), at higher stresses dislocation motion becomes important. Since dislocation motion involves a non-linear stress-strain relationship, the effect of Weertman's conclusion was to overthrow the idea of Newtonian flow in the mantle. His analysis also revealed

a much slower variation of viscosity with depth than that derived from diffusion creep. Specifically, lower mantle viscosity was no higher than about 10<sup>23</sup> poise, or several orders of magnitude lower than that given by Macdonald. This was not too significant in itself, for Dicke (*J. geophys. Res.*, 74, 5895; 1969) had recently obtained a lower mantle viscosity of 10<sup>22</sup> poise from an analysis of the equatorial bulge and Goldreich and Toomre (*J. geophys. Res.*, 74, 2555; 1969) had suggested a value of 10<sup>22</sup>-10<sup>24</sup> poise to explain polar wandering.

But as Brennen (J. geophys. Res., 79, 3993; 1974) now points out, the more important problem is that the Weertman curve is apparently inconsistent with the original isostatic recovery data upon which McConnell's model was based. To discover whether the theoretical model of Weertman may be reconciled with the observational isostatic data, Brennen has thus carried out a hydrodynamic analysis of isostatic recovery flow in the mantle. He concludes, first, that the rapid increase in viscosity with depth demonstrated by McConnell and others is simply a spurious effect resulting from the incorrect assumption of Newtonian flow. The real increase of viscosity is much slower and in general agreement with that predicted by Weertman; certainly the strain rates are higher than Weertman's critical value for the onset of dislocation motion. The best fit between the data and the model is then given by a mantle viscosity which increases with depth as  $\exp(5 \times 10^{-4}z)$ , where z is the depth in kilometres. In short, not only may observation and theory be reconciled, the reconciliation may be taken as evidence that the theory is substantially correct—that is, that mantle flow is non-Newtonian and arises largely from dislocation motion.

### Glassy alloys

from Robert W. Cahn

SINCE times prehistoric, metallurgists have quenched iron or steel in water to harden them. Nowadays they know that the hardness is linked to the presence of a metastable crystal form, containing more carbon in solution than iron should at ambient temperature. This crystal form, martensite, has attracted immense research attention, because the genesis, hardness and breakdown of martensite are all absorbingly interesting scientific problems.

It is surprising, then, that it was not until 1960 that anyone reflected seriously upon the possibility of improving on the fastest rate of quenching then available: dropping a sliver of steel into a bucket of water might cool it at a measly rate of perhaps 1,000° C

per second. It was always a fair guess that the faster one can quench an alloy, the less chance it has to convert to the equilibrium structure and the more likely it is to be fixed in some abnormal and potentially intriguing crystal structure. Yet no one seriously went into the matter until Pol Duwez at California Institute of Technology, in 1960, recognised that the only effective way to speed up cooling rates substantially was to start from the liquid state. He conceived the idea of blasting a small molten drop of alloy by means of a gaseous shock wave against a sloping piece of copper: the technique soon acquired, over the opposition of its fastidious inventor, the onomatopaeic designation 'splat-cooling'. The drop is atomised and then 'splatted' out into a thin liquid layer, which gives up its latent heat to the copper in a very short space of time:

We now know that splat-cooling and related techniques can generate cooling rates from 10<sup>6</sup> to as much as 10<sup>9</sup> degrees C per second. A complete new metallurgy has been created: highly supersaturated solid solutions, a whole zoo of new metastable crystal structures, and glassy alloys have all been developed. Several hundred research papers have recently been reviewed by Jones (Rep. Prog. Phys., 36, 1425; 1973): the work covers not only structures but also anomalous mechanical, electrical and magnetic properties.

Of late, there has been a sudden burst of research on the least understood of the new metallurgical species, glassy alloys. The interest stemmed primarily from the work of David Turnbull at Harvard. Turnbull is renowned for his studies on crystallisation of molten metals, in particular his classic studies on the freezing of molten microspheres. It was a natural transition for him to examine the conditions for the congealing of liquid alloys into a glassy state, uncrystallised. He adopted one of Duwez's early alloys, Pd-Si, which could readily be liquid-quenched to a glassy state, and studied its crystallisation on reheating (for example, Chen and Turnbull, Acta Met., 17, 1021; 1969). Turnbull's ideas then inspired a metallurgist, John Gilman, to more systematic studies. It had already been recognised that alloys of transition metals with metalloids were the most sluggish to crystallise and therefore aptest to form glasses. Gilman became research manager at Allied Chemical Corporation at Princeton and instituted a systematic programme of study. His colleagues, including several of Turnbull's former collaborators, examined a range of alloys based on nickel or iron or mixtures of both, with substantial additions of carbon, boron, phosphorus, silicon and aluminium. They standardised on the 'roller-

quenching' technique: a fine stream of molten alloy impinges on a pair of rollers, very rapidly rotating in contact, and a narrow continuous glassy ribbon emerges. These glasses typically have a glass transition temperature,  $T_{\rm g}$ , in the range of 650-720 K, and a crystallisation temperature, Te, some tens of degrees higher. Polk and Chen (J. Non-Cryst. Solids, 15, 165; 1974) have recently reported on the characteristics of some of these alloys. One generalisation which emerges is that the stablest glasses-that is, those with the largest vaule of  $(T_e - T_g)$ —are those which contain the lowest metalloid content consistent with glass formation. The metalloid solute seems to exert its crystallisation-inhibiting effect by a combination of simple jamming of metal atoms (because the small metalloids fill up the voids between the metal atoms) and strong bonding between solvent and solute, which inhibits displacive rearrangements. Typical compositions include Fe75P15C6Al4 and  $Fe_{38,5}Ni_{38,5}P_{18}B_2Al_3.$ 

The glassy ribbons are extremely strong, with ultimate tensile strengths typically exceeding 200,000 pounds per square inch (Americans are incurably addicted to these venerable units). Several of these alloys, notably nickelbased alloys such as Ni-P-B-C-Al, when the roller-quenching rate was high enough, combined very high strength with measurable ductility (Chen and Polk, J. Non-Cryst. Solids, 15, 174; 1974). This is a unique combination: normally very high strength goes with extreme brittleness, as with fine silicon or carbon fibres. The manufacturers expect to apply their ribbons to reinforcing functions, for instance in car tyres.

The physical mechanism underlying the limited ductility of the alloy glasses is also strikingly novel. Pampillo and Reimschuessel (J. Mater. Sci., 9, 718; 1974) have recently shown that the ribbons deform by a process akin to glide in a metallic crystal. Thin layers of alloy, inclined at 45° to the tensile axis, behave as if they were liquid and the two halves of the ribbon slide over each other. This is probably due to the incipient destruction of short-range (glassy) order and the consequential weakening of resistance to glide. Fracture initiates at several points and the cracks spread along an already defined glide plane, and eventually the cracks collide and the crystal tears apart, showing on the fracture surfaces a pattern of veins which mark the loci along which the cracks collided.

A great deal of work is now in progress on the properties, especially the mechanical behaviour, of these alloy glasses and a number of papers is expected soon in several journals, including the three cited in this survey.

# Flux and composition of micrometeoroids in the diameter range 1–10 $\mu$ m

D. Smith & N. G. Adams

Department of Space Research, University of Birmingham,

H. A. Khan\*

Department of Physics, University of Birmingham, Birmingham B15 2TT, UK

A comparative morphological study of microcraters observed on glassy lunar spherules, and of those created on glassy materials in the laboratory, indicates strongly that 'irons' are the major component of the total flux of micronsized micrometeoroids. This could be because of the differential influence of solar radiation pressure on 'stones' and 'irons'.

We have compared the natural microcraters which occur on glassy lunar spherules with the craters which are produced on these spherules, and on tektite and soda lime glass and quartz crystals, by the impact of hypervelocity solid microparticles from an electrostatic particle accelerator. A scanning electron microscope and an optical microscope were used to measure the depth and diameter of the craters.

### Morphology of craters

We studied a total of 71 craters on 81 light brown, glass spherules (diameters 300–350 μm) from the Apollo 15 fines of less than 1 mm diameter obtained from Spur crater (station 7) near Hadley Rille (sample No. 15301–84). More than 90% of the craters were closely circular in form (indicating near normal incidence) with diameters in the range 1–8 μm and were identified by following the criterion suggested by Hartung et al.¹. Laboratory simulation experiments have shown that at expected impact velocities (several km s<sup>-1</sup>) crater diameters are about 1–3 times larger than the dimensions of the impacting projectile. Therefore, the craters which we have studied should have been formed in micrometeoroid (particles in the micron size regime) impacts.

The crater diameter distribution indicates that the smallest craters are most abundant with a gradual reduction in occurrence with increasing size. A most intriguing result is obtained when the ratio of depth, d, to diameter, D,  $(d|D = \chi)$  of the craters is considered. A histogram of the number of craters $\phi$  within a given range of  $\chi$  (Fig. 1a) indicates that the craters divide into at least two distinct groups. The variation of  $\phi$  with  $\chi$  does not imply a relationship between  $\phi$  and d or D, as there is no correlation between  $\chi$  and d, or  $\chi$  and D. Group I, with a mean  $\chi$  (=  $\chi$ ) = 0.94, Fig. 1a, is distinctly separated from the second major group which itself may consist of two groups, one centred around  $\chi$  = 0.50 (Group II) and another centred around  $\chi$  = 0.33 (Group III) (Fig. 1a). There is some support

for considering the low  $\chi$  grouping as two separate groups: when the data is represented as a plot of d against D (Fig. 2a), three groupings can be recognised, associated with three lines

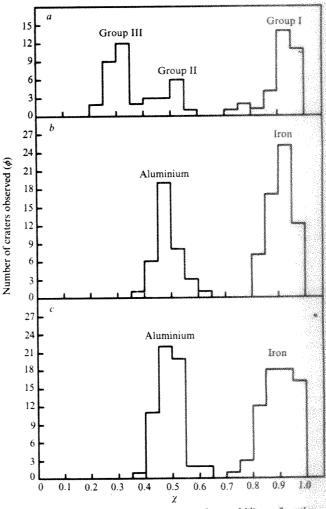

Fig. 1 Histograms of number of craters observed  $(\phi)$  as a function of the crater depth to diameter ratio  $(\chi)$  for: a, natural craters on glassy lunar spherules, showing Groups I, II and III; b, craters produced by the impact of aluminium projectiles on tektite glass and iron projectiles on glassy lunar spherules; c, craters produced by the impact of aluminium and iron projectiles on soda lime glass.

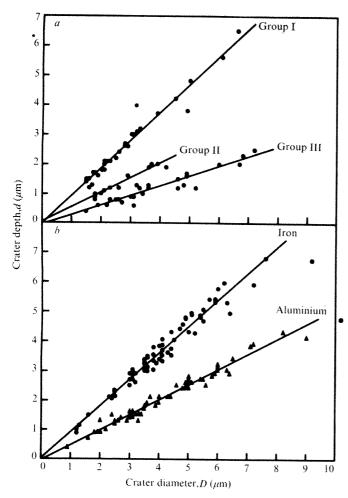

Fig. 2 Depth, d, against diameter, D. The lines are least squares fits to the data points, the slopes of which provide a value for  $\overline{\chi}$ . d, Natural craters on glassy lunar spherules, showing crater Groups I, II and III, with  $\overline{\chi}=0.94\pm0.03,\ 0.50\pm0.04$  and 0.33  $\pm0.02$ , respectively; b, craters produced by the impact of iron and aluminium projectiles on soda lime glass, with  $\overline{\chi}=0.89\pm0.02$  and 0.51  $\pm0.01$ , respectively.

of differing slope. The slopes of the least squares fits for the three sets of data provide a convenient means of expressing  $\bar{\chi}$  for each group, and are in fact those already given. The intercept of each fitted line passes closely through the zero of coordinates; when Groups II and III are considered together the fitted line has a slope smaller than either II or III separately, and a relatively large positive intercept on the d axis. We feel that that is supporting evidence in favour of two separate groups. Figure 2a also indicates that the crater diameters in Group II have lower values than either of the other two groups, but this may be because of the relatively smaller number of

samples. The average crater diameters are: Group I, 2.8  $\mu m$ ; Group II, 2.7  $\mu m$ ; Group III, 3.8  $\mu m$ .

On that basis we speculate that the three crater types either result from three groups of micrometeroids possessing quite different physical properties (for example, iron and stony types), or from three differing velocity groupings of impacting micrometeroids.

To help us to understand these results we produced craters in soda lime and tektite glasses-chosen because of their similar physical properties to the lunar glasses-by bombardment with iron and aluminium microparticles ( $d = 0.5-6 \mu m$ diameter) which were accelerated electrostatically to impact velocities of 1-7 km s<sup>-1</sup> using a 2 MV Van de Graaff generator<sup>2</sup>. Velocity selection was not available with this apparatus so the microparticle beam contained a distribution of those velocities, with a most probable velocity of about 3 km s<sup>-1</sup>. Approximately 60 craters were studied in each case and striking results were obtained when  $\phi$  was plotted against  $\chi$ . Figure 1b shows the histogram peaks for the impact of iron on lunar glass, and aluminium on tektite glass; Fig. 1c is for both iron and aluminium projectiles on soda lime glass. The correlation of the iron projectile peaks with the Group I craters is obvious; the aluminium projectile peaks correlate with the low  $\chi$  groupings, favouring the Group II natural craters. The limited spread in  $\chi$  for the different glasses suggests that these data can be compared confidently with the natural crater results. Figure 2b shows d against D for impacts of both iron and aluminium projectiles on soda lime glass; the slopes of the least squares fits through the points again provide an appropriate value for  $\bar{\chi}$ . The corresponding data for tektite and lunar glass are of equal quality; the available results for the combinations of projectile and target materials are summarised in Table I.

Iron (density 7.9 g cm<sup>-3</sup>) was chosen as an appropriate projectile material because it clearly has physical properties similar to iron meteoroids3,4 and aluminium was considered suitable because its density (2.7 g cm<sup>-3</sup>) and melting point are similar to those of the stony (chondritic) meteoroids. Lower density materials in the micron size regime are difficult to obtain but data are available in the literature<sup>5,6</sup> for the impact of micron-size polystyrene projectiles (density 1.05 g cm<sup>-3</sup>) in a comparable velocity range (2-14 km s<sup>-1</sup>) on soda lime glass. These data shows a relatively wide scatter in  $\chi$  but it has an average value of 0.22, which, taken with the present data, identifies a trend of decreasing  $\overline{\chi}$  with decreasing density of the projectile material. Mandeville has also obtained data for the impact of aluminium projectiles on soda lime glass under conditions similar to those maintained during our work, and be obtained an average value for  $\chi$  of 0.47, in close agreement with our result.

### Nature of impacting particles

Is that sufficient evidence to suggest that the three groups of natural craters originate from physically different micro-

Table 1 Data obtained for craters produced in the laboratory by the impact of microparticles of iron, aluminium and polystyrene on several target materials

meteoroids? The greatest weakness of this argument is the lack of information on the functional variation of  $\chi$  with impact velocity and the doubt about whether laboratory impact velocities are appropriate to micrometeoroid lunar impacts. The concensus is that the impact velocities of lunar micrometeoroids lie in the range 5-20 km s<sup>-1</sup> (refs 1 and 7-9, and Johnson, J. H., et al., unpublished). Thus, we feel that our impact velocities are acceptable, and the small amount of information concerning the variation of  $\chi$  with impact velocity tends to show only a weak velocity dependence of  $\chi$  in the appropriate velocity range. Thus, it may well be that the broadening of the  $\phi$  against  $\chi$  histogram peaks (Fig. 1) is partly because of the finite velocity spectrum both in the natural and laboratory produced craters.

On the basis of the experimental evidence and reasoning already discussed here, we suggest that the three natural crater groupings result from the impacts of micrometeoroids of distinctly different physical properties. Group I craters with the high ₹ values—the least contentious case—we ascribe to high density particles; most probably iron micrometeoroids. Groups II and III we ascribe to the impact of low density microparticle material such as the stony and carbonaceous chondrite material, or even ice crystals<sup>10</sup>. Further deductions can be made by reference to Fig. 3 in which the densities of the laboratory iron, aluminium and polystyrene microparticles are plotted against the  $\chi$  values of the laboratory craters produced on soda lime, tektite and lunar glasses. The curve has been fitted through the origin of the coordinates. If the presented data are interpreted literally, then Group II of the natural craters would seem to be formed by micrometeoroids with effective densities in a limited range, centred about 3 g cm<sup>-3</sup>. On this evidence the Group III natural craters are apparently formed by particles with densities of 1-2 g cm<sup>-3</sup> (allowing for errors of extrapolation) and it is possible that they may result from very low density porous material ('spongy' micrometeoroids). It has often been speculated that very low density material forms a significant component of micrometeoritic material<sup>11,12</sup> and the present data suggest that about 40% of the total flux of the micrometeoroids in this particular particle size range are of this low density (Group III). We consider that of the 71 natural craters, 33 can be assigned to Group I (iron type), 12 to Group II and 26 to Group III. It follows, therefore, that about 40-50% of the particle flux is iron micrometeoroids.

An indication of the mass distribution between the three groups can be obtained if the micrometeoroid sizes can be

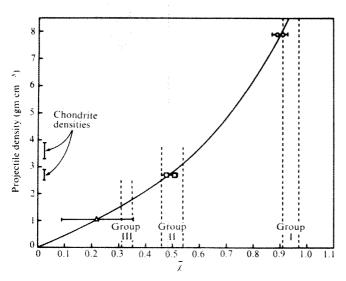

Fig. 3 Plot of projectile density against  $\widehat{\chi}$  for artificially accelerated microparticles.  $\bigcirc$ , iron;  $\bigcirc$ , aluminium;  $\triangle$ , polystyrene; from the data given in Table 1. The horizontal error bars represent the standard error of the mean. The vertical dashed lines indicate the spread in  $\chi$  of the Groups I, II and III natural craters on the lunar spherules.

estimated. Laboratory experiments have shown that the average ratio, η, of crater diameter to projectile diameter, is related to the density of the projectile material, but is essentially independent of velocity. That  $\eta$  is independent of velocity is supported by McDonnell et al.13 who studied the impact of iron projectiles on lunar rock in the velocity range 3-11 km s<sup>-1</sup>. Table I summarises the averaged values of  $\eta = \eta$  obtained for the impact of the microparticles of the three different materials on several target materials. For the glassy lunar spherules, data for iron projectiles only is available but, as can be seen (Table 1), the value of  $\eta$  is closely similar to that for the impact of iron projectiles on (the very similar) tektite glass. Therefore, we have assumed that glassy lunar spherules and tektite glass behave in the same way under bombardment by particles. Data for polystyrene projectiles are only available for soda lime glass and so we have deduced a value of  $\eta$  for polystyrene on to glassy spherules. The value of η for iron on tektite glass, and glassy spherules, is about 75% of that for iron on soda lime glass (Table 1). The same percentage also applies to aluminium projectiles on to these two target materials; itself an interesting result. We therefore assume that this same fraction applies to polystyrene projectiles on to soda lime and tektite glasses, resulting in a value of n for polystyrene onto tektite, and thus lunar glass, of about unity. Thus, we estimate that for lunar glasses the appropriate values for  $\widetilde{\eta}$  are:  $\widetilde{\eta}_{Fe}\approx 2.1;\ \widetilde{\eta}_{Al}\approx 1.4;\ \widetilde{\eta}_{poly}\approx 1.0.$  For these deduced ratios we estimate that the mean micrometeoroid diameters,  $D_m$ , are: Group I,  $D_m = 1.3 \mu m$ ; Group II,  $D_m = 2.0 \, \mu \text{m}$ ; Group III,  $D_m = 3.8 \, \mu \text{m}$ . It follows, therefore, that the mass distribution can be estimated.

The result indicates that about 20% of the total mass of the micrometeoroid material is associated with Group I (iron) micrometeoroids, and that the remaining 80% is divided between the low density (stony) Groups: II (10%) and III (70%). That is not an unreasonable result when compared with other estimates of the meteoric material in the Solar System<sup>4</sup>. That the large percentage of the mass of micrometeoritic material apparently exists in the low density form is, however, of considerable interest, although the results indicate that the density does not fall towards the very low densities inferred by Verniani<sup>2</sup> who observed radio meteors (mean density  $\approx 0.3$  g cm<sup>-3</sup>). Radio meteors are, however, substantially larger, and it does not seem unreasonable to speculate that if such relatively large pieces of 'spongy' material disintegrate to produce smaller micrometeoroids, then somewhat higher density particles may result. It should be noted, however, that very shallow microcraters ( $\chi \leq 0.1$ ) would be very difficult to recognise using our techniques, so craters produced by very low density material may be undetectable.

It could be argued that the low  $\chi$  Group (III) craters are formed by projectiles of lunar origin, that is, ejecta fragments with velocities lower than the lunar escape velocity,  $\leq 2 \text{ km s}^{-1}$ . Hartung et al. have discussed in some detail the possible role of ejecta and they concluded on the basis of estimated relative frequencies of impact and velocity spectra of both ejecta fragments and micrometeoroids, that most microcraters, especially those containing melted host material (the type of craters we examined) are attributable to the impact of micrometeoroids. Also, no spherules with diameters smaller than several tens of microns have been found in these lunar soils, which suggests that ejecta of micron size is not produced in significant amounts. We therefore conclude that Group III craters are caused by micrometeoroids.

In similar studies of depth-diameter ratio Brownlee et al.\* apparently obtained significantly different results. They studied 68 craters with diameters of 0.2-100  $\mu$ m and found no obvious dependence of  $\chi$  on crater diameter (as in all of our studies) They did, however, find a larger dispersion in  $\chi$  among the smaller craters (< 4  $\mu$ m), but they suggested that this may have been because of increased measurement difficulties for the smaller features. They therefore considered the depth-diameter ratio of only those craters with diameters greater

than 4  $\mu$ m (34 craters), and the resulting histogram of  $\phi$  against  $\chi$  shows an obvious peak at  $\chi=0.7$ . They concluded that this represented evidence against significant numbers of micrometeoroids with densities as high as iron; the majority of particles had densities of 2-4 g cm<sup>-3</sup>. They also concluded that the absence of very shallow craters ( $\chi<0.2$ ) suggests that projectiles of very low density (<1 g cm<sup>-3</sup>) are nonexistent or very rare. This very significant result is in complete accord with our data (Fig. 1a) but is in sharp contrast to most meteoroid deceleration data<sup>12</sup>. Their major deduction concerning the density of microparticles seems at variance with our result. A plausible explanation of this apparent discrepancy is, however, possible when it is seen that the two sets of data refer to significantly different mean crater diameters (our work: 3  $\mu$ m; Brownlee et al.: 19  $\mu$ m) and we are, therefore, dealing

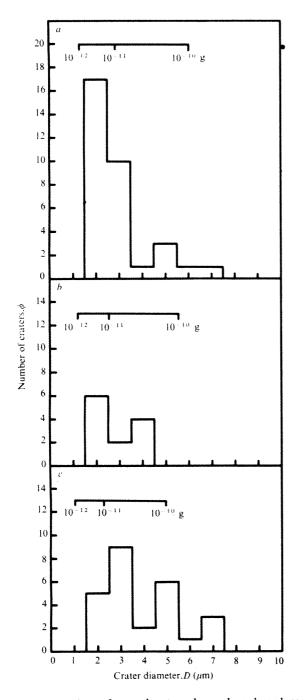

Fig. 4 The numbers of natural craters observed on glassy lunar spherules as a function of the crater diameter for Groups I, II and III (Fig. 1). The equivalent micrometeoroid masses calculated from the inferred material densities are indicated for each group. a, Group I  $(\overline{\chi}=0.94)$ ; b, Group II  $(\overline{\chi}=0.50)$ ; c, Group III  $(\overline{\chi}=0.33)$ .

**Table 2** Data relating to the natural microcraters observed on the sample of glassy lunar spherules

Number of craters observed $\frac{D_{m}}{\chi}$ (µm)  Deduced density (g cm <sup>-3</sup> ) Deduced $\eta$	Group I	Group II	Group III
	33	12	26
	2.8	2.7	3.8
	0.94	0.50	0.33
	8	3	1-2
	2.1	1.4	1.0
Deduced range of particle diameters (µm) Deduced mass range (g × 10 <sup>12</sup> )	0.7–3.1	1.3-2.9	1.5-7.2
	1.5–130	3.3-36	2.7-290

with micrometeoroids in quite separate size and mass ranges. Using an  $\tilde{\eta}$  of 1.4 we estimate that the average micrometeoroid size appropriate to the Brownlee *et al.* data is about 14  $\mu$ m, and so in the case of the low density particles (2–4 g cm<sup>-3</sup>) we are dealing with an average difference in mass of about 100 times between the two sets of data.

Figure 4 shows the  $\phi$  against D histograms for the three groups of natural craters. A very rapid increase in  $\phi$  with decreasing D is apparent for the Group I iron micrometeoroids (Fig. 4a). This, coupled with the low density Group III data (Fig. 4c) which, within the statistical fluctuation, indicate a much slower increase in  $\phi$  with decreasing D, strongly suggests an increasing contribution of iron type micrometeoroids to the total micrometeoroid flux in the micron size region. Little can be said about the Group II data (Fig. 4b) except that they do not seem to conflict with the general conclusions drawn for the other two groups. Accordingly, we suggest that the nature of micrometeoritic material is strongly dependent on the region of the mass spectrum being considered, the proportion of low density stony material decreasing and the proportion of high density iron particles increasing with decreasing particle size in the 0.5-8 µm diameter range. This conclusion is most forcibly demonstrated in Fig. 5 in which the absolute differential fluxes of the Groups I and III micrometeoroids are plotted against mean particle diameter. The three points on each curve were obtained by summing the total number of craters observed in the intervals of crater diameter 1.5-3.5  $\mu m$ , 3.5-5.5  $\mu m$ , and 5.5-7.5 µm, and deducing the mean particle diameters using the appropriate values of  $\bar{\eta}$  (Table 1). The absolute differential flux was obtained from a consideration of the total number of particles observed in each group, the scanned area of the lunar spherules and the estimated exposure time to micrometeoroid bombardment. The last was estimated using the technique<sup>14</sup> of charged particle track analysis. The detailed form of the two curves cannot be interpreted too literally because of the limited amount of data from which they were derived. We believe, however, that the gross features are significant, and indicate that for a particle diameter in excess of about 2 µm, the major fraction of the micrometeoroid flux consists of low density material. The reverse seems to be the case for particle diameters approaching 1 µm, where the high density microparticles predominate. This most interesting feature of the data is quite consistent with the often predicted, but to our knowledge never observed, effects of solar radiation pressure, which acts against solar gravity to exclude very small particles from the Solar system. This pressure is differential in that it acts to a greater extent on low density materials and is thus expected to influence the flux of the Group III micrometeoroids to a greater extent than those of Group I. The magnitude of the radiation pressure effect is traditionally referenced to the particle mass for a given density of material, and so the equivalent mass scales for the two groups-which are not common because of the different material densities of the two groupsare also included in Fig. 5. These results were obtained from simple classical theory<sup>15</sup>. Thus, for 2 µm diameter particles the effect is predictably severe on the Group III particles and the reducing slope of the Group III curve of Fig. 5 probably reflects the increasing effect with decreasing size (mass). The

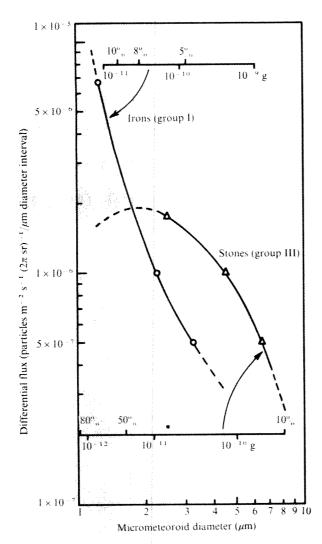

Fig. 5 Differential micrometeroid flux as a function of micrometeroid diameter for irons (Group I) and stones (Group III). The equivalent mass scale and a percentage index of the effect of solar radiation pressure are also indicated for each group. The percentages indicate the magnitude of the outward force resulting from solar radiation, relative to that of solar gravity at 1 AU. Thus, at 50% the former is half of the latter.

extrapolation of the curve (dashed) is simply a recognition of the fact that when the radiation pressure effect exceeds 100% (that is, exceeds gravity) then a 'cut off' results and no particles below a given mass ( $\approx 4.10^{-13}$  g) or diameter (0.8 µm for a material density of 1.5 g cm<sup>-3</sup>) can exist in stable orbits in the Solar System. For Group I particles of 2 µm diameter, radiation pressure effects are small (a few percent) and thus the differential flux of iron micrometeoroids continues to increase even at very small particle diameters, until the classical 'cut off' at about  $0.2 \, \mu m \, (2.10^{-14} \, g)$  is approached.

The number of craters which we observed per cm<sup>2</sup> of the lunar glasses agrees well with that of Brownlee et al.9: (both samples were from the Apollo 15 sites). We found approximately  $3\times10^3$  craters cm  $^{-2}$  in the diameter range 1.5–7.2  $\mu m$ whereas the Brownlee et al. found  $7 \times 10^3$  cm<sup>-2</sup> in the same diameter range. They found an increasing incidence of small craters with decreasing crater diameter, with the cumulative crater surface number density approximately  $5 \times 10^4$  cm<sup>-2</sup> at a crater diameter of 0.3  $\mu$ m. An extrapolation (on a log  $\phi$  against log D plot) of our Group I data (Fig. 4a) to a crater diameter of 0.3 µm (that is, to particle diameters near to the classical solar radiation pressure limit) indicates a cumulative number density of  $\sim 7 \times 10^4$  craters cm<sup>-2</sup>. The similarity of these estimates tends to indicate that the smaller features in the Brownlee et al. data were produced by the impact of iron

micrometeoroids, because similar extrapolation of the Group III data (stony types) indicates much smaller number densities for crater diameters of less than 1 μm.

Of much greater interest in meteorite studies is the cumulative flux of micrometeoroids at any given mass, and how this parameter varies with mass. The cumulative flux of all micrometeoroids above a mass of 10<sup>-11</sup> g is indicated by the present data to be approximately  $2 \times 10^{-5} \, \text{m}^{-2} \, \text{s}^{-1} \, (2\pi \, \text{sr})^{-1}$  using the derived exposure time to meteorite impact of ~ 5.104 yr (ref. 14). This result compares very favourably with the satellite data of Alexander et al. reported by Hughes16, which suggests a value of  $\sim 5 \times 10^{-5} \text{ m}^{-2} \text{ s}^{-1} (2\pi \text{ sr})^{-1}$  at  $10^{-11} \text{ g}$ . The very great difference in the effective sampling time between the satellite experiments (~ 1 yr) and the present 'crater technique' seems to suggest that the micrometeoroid flux has remained sensibly time invariant during the recent history of the Solar System.

A further important result is obtained if the cumulative crater data at the classical solar radiation pressure limit (obtained by applying the extrapolation procedure to the Group I data) is converted to cumulative micrometeoroid flux. The value thus indicated at a micrometeoroid mass of 10<sup>-14</sup> g is approximately  $10^{-3}$  m<sup>-2</sup> s<sup>-1</sup>  $(2\pi$  sr)<sup>-1</sup>. If the mass limit of solar radiation pressure for iron micrometeoroids were lower than that predicted by the classical theory, then it is likely that relatively large fluxes of very small iron micrometeoroids ( $d < 0.1 \mu m$ ) could exist in stable orbits in the Solar System. Highly sensitive detectors would be necessary to verify the existence of such small particles, such as the plasma micrometeoroid detector<sup>47</sup> incorporated into the Prospero satellite18 which did, in fact, indicate a total cumulative flux at its predicted threshold mass sensitivity of  $10^{-15}$  g in the range  $10^{-2}$  to  $10^{-1}$  m<sup>-2</sup> s<sup>-1</sup>  $(2\pi$  sr)<sup>-1</sup>.

Our study indicates that the differential flux of iron type micrometeoroids increases rapidly as their size reduces progressively to diameters below about 2 µm. For micrometeoroid diameters  $\geq 2 \mu m$ , micrometeoroids with a density of 1-4 g cm<sup>-3</sup> increasingly contribute to the flux, until they represent in excess of 90% of the total. The available evidence indicates that the major component of the flux at this low density grouping is of material in the density range 1-2 g cm with a smaller component at a density near to 3 g cm<sup>-3</sup>. Thus, the data seem to support the accepted view that iron type meteoroids represent only a very small fraction of the total mass of meteoritic material. In the diameter range 0.1 µm-1.0 µm, however, a large fraction of the total flux of micrometeoroids must be of the high density iron type and their cumulative flux at the lowest mass may approach the relatively high values indicated by the most sensitive micrometeoroid detectors.

We acknowledge the cooperation and help of Dr S. A. Durrani (NASA Principal Investigator), Professors A. P. Willmore, and J. H. Fremlin and Dr D. K. Bedford. We also thank Mr R. I. Phillips for assistance with data acquisition and analysis. We gratefully acknowledge the financial support of the Science Research Council.

### Partial nucleotide sequence of a prokaryote initiator tRNA that functions in its non-formylated form

Ann S. Delk & Jesse C. Rabinowitz

Department of Biochemistry, University of California, Berkeley, California 94720

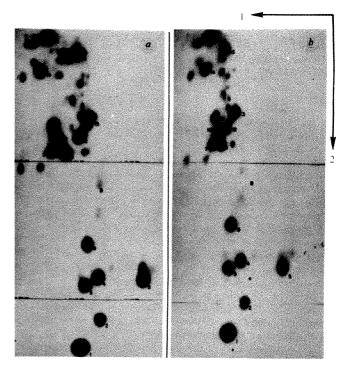

When grown in the absence of folate, Streptococcus faecalis initiates protein synthesis with non-formylated . methionyl-tRNA1 Met. The nucleotide sequence of this tRNA differs from that of tRNAi Met synthesised in the presence of folate — which functions as N-formylmethionyl-tRNA: Met—only in the 'GT\psiC' loop, where uracil is found in the tRNAi Met of folate-free cells in place of thymine.

Initiation of protein synthesis in the bacterium Streptococcus faecalis R is an interesting exception to the generalisation concerning the difference in this process in prokaryotes and eukaryotes. Initiation of protein synthesis in all prokaryotes and certain organelles of eukaryotes appears to involve a special tRNA, tRNA, that functions as a formylated methionylated derivative, N-formyl-methionyl $tRNA_{\rm f}^{\rm Met}$ , and donates a formyl-methionyl residue to the N-terminus of the peptide chain<sup>1-3</sup>. The formyl group essential for the initiation process is transferred to methionyltRNA<sub>f</sub><sup>Met</sup> from a derivative of folic acid, 10-formyltetrahydrofolate, by means of a specific enzyme<sup>4,5</sup>. Initiation of protein synthesis in the cytoplasm of eukaryotes also involves a unique tRNA Met species. However, formylation of eukaryotic methionyl-tRNA, Met does not occur in vivo, although methionyl-tRNA $_{i}^{Met}$  from some eukaryotes can be formylated in vitro by the transformylase of Escherichia coli³.

S. faecalis cannot synthesise folate or its derivatives de novo and normally requires the presence of one of these substances in the growth medium. The organism, however, can grow at essentially the normal rate in the absence of any of these compounds when the growth medium contains serine, methionine, thymine, a purine base and pantothenate6, each substance a product of a synthetic pathway involving a folate derivative7.8. N-formyl-methionyl $tRNA_f^{Met}$ , considered to be essential for initiation of protein synthesis in bacteria<sup>1-3</sup>, is also a product of an enzymatic reaction involving a folate derivative4.5. However, it is not necessary to supply the organism with this substance when it is grown in folate-free medium. Samuel et al.9-11 demonstrated that under these growth conditions, initiation of protein synthesis proceeds with non-formylated methionyl-tRNA<sub>f</sub><sup>Met</sup> and appears in this respect to resemble the protein initiation process in eukaryotes. Their data showed that the ability of this bacterium to initiate protein synthesis with non-formylated methionyl-tRNA<sub>f</sub><sup>Met</sup> is attributable to an alteration in the tRNA<sub>t</sub>Met, and not to a modification of the ribosomes or factors involved in protein initiation. The tRNA<sub>f</sub>Met of S. faecalis grown in the absence

of folate can be distinguished from the tRNA<sub>1</sub>Met of S. faecalis grown in the presence of folate by several physical, chemical and biological criteria. Of particular significance is the observation that non-formylated methionyl-t $RNA_f^{Met}$ from minus-folate cells forms an initiation complex with ribosomes, poly (A,U,G), and initiation factors under conditions where methionyl-tRNA<sub>1</sub>Met from plus-folate S. faecalis, like other prokaryotic initiator tRNAs, requires prior formylation for formation of the initiation complex<sup>11</sup>.

Sequence analyses have been undertaken in several laboratories in efforts to identify structural features of the tRNA Met species that are responsible for their different biological properties. The nucleotide sequences of two isospecies of tRNA<sub>f</sub><sup>Met</sup> and two of tRNA<sub>Met</sub> from E. coli have been determined<sup>12-14</sup>. More recently the sequences of the tRNA<sub>1</sub>Met from yeast<sup>15</sup> and three mammalian sources<sup>16,17</sup> have been reported. The tRNA<sub>f</sub>Met sequences of the mam-

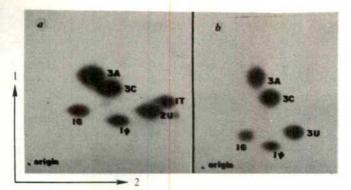

Fig. 2 Two-dimensional fractionation of 3' nucleotides obtained by combined pancreatic RNase and T<sub>2</sub> RNase digestion of oligonucleotide U-16 from (a) plus-folate and (b) minus-folate S. faecalis tRNA<sub>1</sub><sup>Met</sup>. (1) First dimension: isobutyric acid-NH<sub>4</sub>OH; (2) second: isopropanol-HCl-H<sub>2</sub>OI<sup>9</sup>. Bases are identified by standard letter designations with a numeral indicating the number of equivalents found.

malian cells are identical and show a high degree of homology with  $E.\ coli\ tRNA_1^{\rm Met}$ , as well as with yeast  $tRNA_1^{\rm Met}$ , that is suggested to reflect the special constraints in evolutionary divergence that the unique role of this tRNA has imposed. An unusual feature of eukaryote  $tRNA_1^{\rm Met}$  is the lack of a  $GT\psi C$  sequence in loop  $IV^{1s-17}$ . It was thus of particular interest to note that the  $tRNA_1^{\rm Met}$  of  $S.\ faecalis$  grown in the absence of folate does not contain ribothymidine (T), whereas  $tRNA_1^{\rm Met}$  from cells grown with folate does contain this modified nucleoside. We have therefore investigated the more detailed chemical structure of  $tRNA_1^{\rm Met}$  of  $S.\ faecalis$ .

S. faecalis was grown in the presence (plus-folate) or in the absence (minus-folate) of folic acid in a low phosphate medium containing <sup>32</sup>P-phosphate, a modification of a medium described previously <sup>30</sup>. Cells were collected by centrifugation and then broken by sonication. Unlabelled carrier tRNA was added and the tRNA<sub>f</sub> <sup>Met</sup> was isolated and purified essentially as described elsewhere <sup>31</sup>. The final tRNA<sub>f</sub> <sup>Met</sup> sample was estimated to be 80–90% pure.

The tRNA<sub>1</sub><sup>Met</sup> was analysed as described by Barrell<sup>18</sup>, except that U<sub>1</sub> RNase, a gift of Drs A. Blank and C. A. Dekker, was used instead of T<sub>1</sub> RNase and frequent use was made of the two-dimensional thin-layer chromatography system for nucleotides described by Nishimura<sup>19</sup>. The detailed data of this investigation will appear elsewhere. As suggested by Barrell<sup>18</sup>, except where stated otherwise, the letters A, C, G, and U are used for the 3' nucleotide residues and a sequence such as ACG represents ApCpGp. Parentheses enclosing letters indicate that the sequence of these nucleotides is unknown.

Two-dimensional thin-layer chromatography<sup>19</sup> of this 3' nucleotides obtained on enzymatic digestion showed that, in addition to the four major nucleosides, plus-folate  $tRNA_I^{Met}$  contains one T, one pseudouridine ( $\psi$ ), and one dihydrouridine (hU), whereas minus-folate  $tRNA_I^{Met}$  contains only one  $\psi$  and one hU.

As Fig. 1 shows, the fingerprints of the oligonucleotides obtained by digestion of plus-folate and minus-folate  $tRNA_1^{Met}$  with  $U_1$  RNase were essentially identical, indicating that the sequence of the two tRNAs are similar. Analysis of the oligonucleotides showed that the compositions of corresponding fragments were the same for both tRNAs except for oligonucleotides 16 (designated U-16) which, as seen in Fig. 2, was shown by two-dimensional thin-layer chromatography to have a composition  $(T\psi U_2C_3A_3)G$  in plus-folate  $tRNA_1^{Met}$  and  $(\psi U_3C_3A_3)G$  in minus-folate  $tRNA_1^{Met}$ , suggesting that in the latter case a single U residue had not undergone methylation to produce T (5 methyluridine).

As Fig. 3 shows, fingerprints obtained on pancreatic

RNase A digestion were also quite similar for the two tRNAs, establishing the sequence similarity. In plus-folate tRNA<sub>1</sub><sup>Met</sup>, T was found in oligonucleotide 12 (P-12), the composition of which was shown to be (AG<sub>2</sub>)T. The corresponding oligonucleotide from minus-folate tRNA<sub>1</sub><sup>Met</sup> had the expected composition (AG<sub>2</sub>)U. All other oligonucleotides examined had identical composition for the two tRNAs. Attention was thus focused on the sequence surrounding T from plus-folate tRNA<sub>1</sub><sup>Met</sup> and the corresponding sequence from the minus-folate tRNA<sub>1</sub><sup>Met</sup>.

On further digestion of the U-16 oligonucleotides with pancreatic RNase, both the plus-folate and minus-folate fragments yielded one equivalent of A3U, one equivalent of G, and three equivalents of C; however, the plus-folate sample yielded an equivalent each of T,  $\psi$ , and U, whereas the minus-folate sample gave one equivalent of  $\psi$  and two equivalents of U. On partial digestion with U2 RNase, both samples yielded (U2C2)G, A3, A2 and A fragments. However, plus-folate U-16 yielded the oligonucleotides  $(T\psi CA)$  and  $(T\psi C)$ , whereas the corresponding minus-folate fragments were  $(U\psi CA)$  and  $(U\psi C)$ . After removal of the phosphate from the unexpected but consistently obtained U2 RNase digestion product (UψC), pancreatic RNase digestion produced U and  $\psi$ , indicating that Comwas at the 3' end of the dephosphorylated fragment, this base having been released as the nucleoside and thus undetected by autoradiography. From these data one can deduce the sequence (Tψ)CAAAU(CCU)G for the oligonucleotide U-16 from plus-folate tRNA<sub>f</sub><sup>Met</sup> and (Uψ) CAAAU(CCU)G for the corresponding oligonucleotide from minus-folate tRNA<sub>f</sub>Met.

The final sequence was derived by analysis of the pancreatic RNase product P-12 from plus-folate tRNA<sub>1</sub><sup>Met</sup>, the composition of which is (AG<sub>2</sub>)T. The T is automatically assignable to the 3' end by nature of pancreatic RNase specificity. After removal of the 3' phosphate, snake venom phosphodiesterase treatment yielded pG and pT in the ratio 2: 1, thus establishing the sequence as AGGT. Since there is only one T in plus-folate tRNA<sub>1</sub><sup>Met</sup>, oligonucleotides P-12 and U-16 must overlap and T must be at the 5' end of the oligonucleotide U-16. Figure 4 shows the derived sequence of what is apparently the 'GTΨC' loop (IV) and stem of tRNA<sub>1</sub><sup>Met</sup> of S. faecalis.

This sequence bears striking resemblance to the 'GT\square\C'

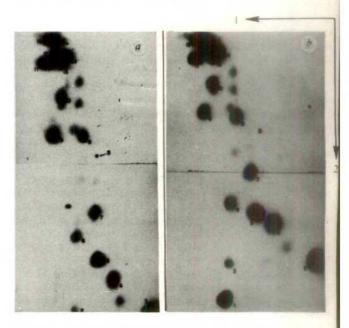

Fig. 3 Autoradiograph of two-dimensional fractionation of pancreatic RNase digestion products of (a) plus-folate and (b) minus-folate S. faecalis tRNA<sub>r</sub><sup>Met</sup>. (1) and (2) as in Fig. 1.

B indicates position of blue marker.

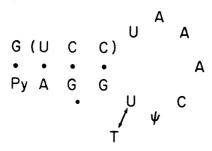

Fig. 4 Nucleotide sequence of the presumed loop IV and stem of tRNA<sub>1</sub><sup>Met</sup> from minus-folate S. faecalis (primary sequence) and tRNA<sub>1</sub><sup>Met</sup> from plus-folate cells (T replacing U).

arm of tRNA<sub>f</sub><sup>Met</sup> of E. coli<sup>13</sup>, the only difference being that in the E. coli tRNA a G-C pair is found in place of the presumed U-A base pair in the stem of the S. faecalis tRNA. Recently it has been shown that the single-stranded portion of the 'GT\(psi C'\) arm of Anacystis nidulans tRNA<sub>t</sub> Met has this same base sequence20.

The similarity in the U<sub>1</sub> RNase digestion products of the plus-folate and minus-folate tRNAs in combination with the similarity of their pancreatic RNase digestion products indicates that the remainder of the nucleotide sequence is identical for the two S. faecalis tRNAs. Although the complete sequence of tRNA<sub>1</sub>Met of S. faecalis has not been determined, a comparison of its enzymatic digestion products with those of tRNA<sub>f</sub><sup>Met</sup> of E. coli<sup>12</sup> indicates that there is a great deal of similarity between these two molecules.

Like tRNA<sub>f</sub><sup>Met</sup> of E. coli, the S. faecalis tRNA has pCG (oligonucleotide U-7) at the 5' terminus. It is not known, however, if the terminal C is hydrogen bonded to a G residue since there is uncertainty about the sequence of the 3' end of the tRNA. Oligonucleotide U-5, which has the composition (A<sub>2</sub>C<sub>3</sub>), is identifiable as the 3' terminus by its lack of G. Presumably it contains an undetectable AoH and has the sequence (CA2)CCA0H. The composition of this oligonucleotide is identical to that of the fragment CAACCA<sub>OH</sub> obtained upon T<sub>1</sub> RNase digestion of tRNA<sub>f</sub><sup>Met</sup> from E. coli<sup>12</sup>. Oligonucleotide U-5 migrates differently, however, in the second dimension from what was reported for CAACCA<sub>OH</sub><sup>12</sup>. Although the mobility of U-5 is similar to that reported for CCACCAOH20, reproducible quantitative data indicate that this is not the composition of the S. faecalis fragment. The 5' terminal residue of S. faecalis tRNA<sub>i</sub>Met, like that of tRNA<sub>i</sub>Met of E. coli<sup>13</sup> and A. nidulans20 and unlike that of most other tRNAs examined, is not hydrogen bonded to a residue four nucleotides removed from the 3' AoH. It is not known at this time, however, if the 3' terminus of S. faecalis tRNA<sub>f</sub><sup>Met</sup> is identical to or similar to that of E. coli tRNA<sub>f</sub> Met or if the 5' C is hydrogen bonded to a G that is more than four nucleotides removed from the 3' AoH.

At least a portion of the hU loop appears identical for E. coli and S. faecalis tRNA<sub>f</sub> namely, both have a single hU which occurs in the sequence GGhUAG13. (The sequence of the S. faecalis oligonucleotide P-11 is GGhU, that of U-9 is hUAG.) S. faecalis tRNA, Met on U1 RNase digestion yields (C2U)G (U-12) and on pancreatic RNase figestion AGC (P-7). These two could be from the hU loop and would be consistent with a sequence identical to that of the E. coli tRNA, namely CAGCCUGGhUAG13, the first ind last bases forming a hydrogen bond.

Oligonucleotide U-15 has the composition (A<sub>3</sub>C<sub>5</sub>U<sub>2</sub>)G and nay be from the anticodon loop since E. coli tRNA, Met on  $\Gamma_1$  RNase digestion yields the anticodon-containing oligonucleotide 2'OMeCUCAUAACCCG12. The pancreatic RNase product P-13 from S. faecalis has the sequence GGGC. These two products would be consistent with an inticodon loop and stem similar to that of the E. coli tRNA with the notable exception that tRNA; Met of S. faecalis does

not have 2'OMeC. Furthermore, although both isospecies of tRNA<sub>f</sub>Met from E. coli contain 4-thiouracil and one contains 7-methylguanine<sup>13</sup>, tRNA<sub>f</sub>Met from plus-folate S. faecalis has no modified bases other than T,  $\psi$ , and hU and tRNA<sub>1</sub>Met from cells grown in the absence of folate has only  $\psi$  and hU. S. faecalis  $tRNA_f^{Met}$  has the smallest number of modified bases observed among tRNAs.

Analysis of unfractionated and partially fractionated S. faecalis tRNA showed that the absence of T is not unique to the tRNA<sub>f</sub>Met species. Although T is present in tRNA from plus-folate cells, this modified residue is absent in all tRNA species of S. faecalis when it is grown in folate-free medium.

In summary, tRNA<sub>1</sub>Met of S. faecalis is similar in sequence to tRNA<sub>1</sub>Met of E. coli, although S. faecalis tRNA<sub>1</sub>Met lacks several modified bases found in the E. coli species. When grown in the presence of folate, S. faecalis tRNA<sub>1</sub>Met contains the modified base T in the sequence  $GT\psi C$ . When the bacterium is grown in the absence of folate, methylation of the specific U residue does not occur, the resulting sequence being  $GU\psi C$ . The remainder of the nucleotide sequence is identical for plus-folate and minus-folate S. faecalis  $tRNA_{\rm f}{}^{\rm Met}.$ 

The absence of this single methyl moiety is sufficient to alter the chromatographic and melting properties of the  $tRNA_{\rm f}^{\rm Met}$  species and, most significantly, to allow the bacterium to initiate protein synthesis with non-formylated  $methionyl\text{-}tRNA_{\mathrm{f}}^{Met}\quad when \quad 10\text{-}formyltetrahydrofolate, \quad an$ essential component of the formylation reaction, is unavailable. Further investigation is required to determine whether the ability of this tRNA, Met to function in its non-formylated form is the consequence of direct interaction of the altered portion of the tRNA with ribosomes or various factors involved in protein synthesis, or whether it is the result of a conformation change in the tRNA molecule. It would be interesting to examine the tRNA<sub>f</sub><sup>Met</sup> and protein initiation process in the mutants of E. coli which are totally lacking T21 and strains of Bacillus subtilis which are low in T content<sup>22,23</sup> to determine if the absence of T in other prokaryotic initiator tRNAs allows them to function in their non-formylated form.

#### A Newtonian view of relativistic cosmology

In spite of the success of Milne and McCrea1 in using classical mechanics to reproduce the Friedmann universes, the mathematically simplified apparatus of Newtonian cosmology has been of only limited use in exploring relativistic world models. In general, the required formulation of Newtonian universes2.3 leads to indeterminate equations of motion: one has an infinite region of homogeneous dust (density  $\rho(t)$ , pressure p=0), in which the gravitational field cannot be found classically. This letter outlines a way of resolving the indeterminacy, and gaining an insight into relativistic cosmology, through equations that reveal the dynamics of relativistic dust world models in a quasi-Newtonian fashion.

The method is a local-approximation technique using spatial power series expansions in comoving coordinates ( $\xi'$ ,  $\tau$ ). We take a cosmological metric

$$ds^2 = d\tau^2 + 2g_{4i} d\xi^i d\tau + g_{ij} d\xi^i d\xi^j$$
 (1)

and noting the conservation equations  $\partial g_{4i}/\partial \tau = 0$ , we write

$$g_{4i} = E_i + F_{ir}\xi^r + G_i^{rs}\xi^r\xi^s + \dots$$
 (2a)

$$g_{IJ} = M_{IJ} + N_{IJ}^{r} \xi^{r} + \frac{1}{2} P_{IJ}^{rs} \xi^{r} \xi^{s} + \dots$$
 (2b)

Because the coefficients on the right of (2a) are constant, there is a transformation of  $\tau$  that gives  $E_i = 0$  and  $F_{ij} = -F_{ji}$ . M, Nand P are  $\tau$ -dependent arrays, but we can set  $-M_0 = I$  (the  $3 \times 3$  identity matrix) and  $N_0 = 0$  at an initial instant  $\tau_0$ .

A local correlation is then obtained with the usual kinematics of Newtonian universes, in which the velocity v of matter, being a linear function of Cartesian coordinates  $x^{i}$ , is defined by a matrix H depending only on the absolute Newtonian time t. H decomposes into an expansion scalar H, a traceless symmetric shear tensor Q, and an antisymmetric spin tensor W:

$$\mathbf{v} = H\mathbf{x} \colon H = H(t) = \tilde{H}I + Q + W \tag{3}$$

The classical motion is given in Lagrangian coordinates by a matrix A(t). A particle initially at  $x_0$  has the general position  $\mathbf{x} = A\mathbf{x}_{\theta}$ , provided that

$$\hat{A} = HA; \ A_0 = I \tag{4}$$

We can identify the  $x_0^i$  locally with the comoving coordinates  $\xi^{i}$ , and in the local approximation we can also interchange t and τ. With these correspondences, the leading coefficients in equations (2a, b) are found to be the matrices

$$F = -A'WA; M = -A'A \tag{5}$$

This local Newtonian interpretation of a general comoving metric is useful in itself.

Although the classical potential U is indeterminate, the Euler equation shows that it may be written as a quadratic form given by a t-dependent symmetric matrix  $\Phi$ :  $U = \frac{1}{2}\Phi_{ij}x^ix^j$ ;  $\Phi = \Phi(t) = \Phi^{t}$ . The Euler, Poisson and continuity equations reduce to

$$\bar{H} + H^2 + \Phi = 0 \tag{6a}$$

$$tr(\Phi) = 4\pi G \rho$$
 (6b)

$$\dot{\rho} + \rho \operatorname{tr}(H) = 0 \tag{6c}$$

and here the inadequacy of Newtonian mechanics is obvious? we have just one equation for the six independent  $\Phi_{ij}$ . In the absence of spherical symmetry extra conditions may be imposed arbitrarily3-5, but the Φ corresponding to general relativity is far from evident.

But we can get the relativistic answer by extending the localapproximation formalism to Einstein's field equations. With the comoving coordinates chosen locally as before, it turns out that the relativistic potential matrix  $\Phi$ , is given by

$$\Phi_r = \frac{1}{2}\pi G\rho I + \overline{H}Q - (Q^2 - \frac{1}{2}tr(Q^2)I) + \Phi_c \qquad (7a)$$

$$\Phi_{c} = \psi - \frac{1}{3} tr(\psi) I; \ \psi = -(A^{-1})^{t} (\mathring{R}^{0}) A^{-1}$$
 (7b)

where the matrix  $\tilde{R}^0$  is the local value of the Ricci subtensor  $\tilde{R}_{ij}$ of the & 3-spaces. This result shows how matter, motion and spatial curvature contribute to the potential.

The determinate quasi-Newtonian potential with  $\Phi_c=0$  gives an exact description only of universes whose comoving space sections have isotropic curvature: the Bianchi Type I models, a non-rotating subclass of Type V, and the closed Friedmann universe (see ref. 6). But it is interesting that rotating solutions with  $\Phi_{
m e}=0$  need not have a singularity. (This is most easily shown for cylindrical models5.7.) We cannot infer here that similar exact relativistic solutions exist. Given the wide scope of the Penrose-Hawking theorems', the implication is rather that curvature anisotropies are a vital factor in causing singularities

In general the potential remains indeterminate, because  $\Phi_{\epsilon}$ cannot be predicted. (Though  $\Phi_c$  can be calculated for homogeneous universes, since their metrics are known in advance. Nevertheless, the quasi-classical equations are of some heuristic value, and they can be used to classify and elucidate various kinds of singularities and indefinite expansion occurring in relativistic world models. They show in particular why expand ing universes that approach isotropy have to be regarded as unusuals: the shear tensor Q is self-damping during expansion only in the special cases when  $\Phi_c$  is insignificant.

The decisive effects that  $\Phi_c$  may have are exemplified by Bianchi Type VI universes, for which solutions can be generated by computer. Some rotating models of this class exhibit no only anisotropic expansion, but also matter singularities of 'ribbon' form that seems to be hitherto unreported: the princi pal axes of a local comoving ellipsoid tend to zero, a constant and infinity. The limiting behaviour is apparently of power law type, with the volume proportional to  $\tau^p$ , where  $0 , as <math>\tau \downarrow 0$ . (In isotropic singularities p = 2, and velocity-dominated ones have p = 1 if a simple power law applies.)

These Bianchi VI singularities are distinct from the 'whimper' sort<sup>11</sup>, in which the homogeneous 3-spaces of a synchronous coordinate system change their signature. The models referred to here have been studied using a comoving metric of the form (this actually ranges over Types I, III, V, VI)

$$\begin{aligned} ds^2 &= d\tau^2 + 2\lambda \eta d\xi^2 d\tau - \{\alpha (d\xi^1)^2 + 2\nu \eta d\xi^1 d\xi^2 + \\ &+ \beta (\eta d\xi^2)^2 + \gamma (\zeta d\xi^3)^2 \} \end{aligned} \tag{8}$$

where  $\eta = \exp(m\xi^1)$ ,  $\zeta = \exp(n\xi^1)$ ;  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\nu$  are functions of  $\tau$ ;  $\lambda$ , m, n are constants. (see equations (2). The Newtonian interpretation (5) will usually require a local transformation of the metric (8).) The field equations for (8) show that only exceptional cases, if any, can pass through a whimper singularity (corresponding here to  $\alpha\beta = \nu^2$ ), and probably this is true in general.

As for matter singularities, the quasi-Newtonian equations suggest a vast range of possible behaviour in relativistic cosmology, making present observations of radiation isotropy appear all the more remarkable. Details of singularity behaviour and other specialised aspects will be discussed elsewhere.

I thank Professor W. Davidson for encouragement, Dr A. R. King for a copy of ref. 11, and the referee for suggesting the connection with that paper. This work was supported by the University Grants Committee (NZ).

#### Redshifts of Markaryan galaxies

MARKARYAN<sup>1</sup> and Markaryan and Lipovetsky<sup>2</sup> have given data on a few hundred galaxies with strong ultraviolet continua. Markaryan classifies them on the basis of the concentration of the source of the continuum (s means concentrated and d diffuse objects; sd and ds are intermediate). Especially among the s-type objects there seems to be contamination with QSOs when their spectra, colour and presumable morphology (spheroidal, compact) are considered. Redshifts are now available for many Markaryan galaxies providing new material for studies of the redshift problem. It is worthwhile to see whether the claimed peculiarities in redshifts of QSOs and related emission-line objects<sup>3-6</sup> have counterparts in the distribution of these

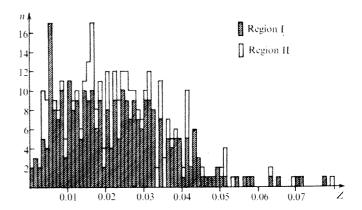

Fig. 1 Distribution of the redshifts of Markaryan galaxies.

smaller redshifts. According to Arp and Sulentic (see ref. 7) many Markaryan galaxies seem to be companions of small-redshift bright galaxies and thus they possibly have anomalous redshifts.

I present here a preliminary survey of the data which consist of 394 redshifts<sup>8-15</sup> (z < 0.08) of which 90, 92, 65, and 147 are for s, sd, ds, and d objects, respectively. The measurements of Ulrich<sup>13</sup> and Sargent<sup>14</sup> were preferred.

The distribution of all the redshifts is presented in Fig. 1, using the interval  $\Delta z = 0.001$ , corresponding to the accuracy of most redshifts. Burbidge<sup>3</sup> and Burbidge and O'Dell<sup>5,6</sup> found for different kinds of emission-line objects peaks near z = 0.03 and z = 0.06. In my analysis no groupings at these values can be seen, probably because of the different class of objects studied.

But there is a peak at z=0.015-0.016, with some interesting features. Its statistical significance can be approximated from Poisson's formula when the gross frequency distribution of the redshifts is taken as rectangular between z=0.003 and z=0.030. The probability that 30 redshifts should fall inside an interval of  $\Delta z=0.002$  is about 0.05. But what really makes such a peak interesting is how its properties are consistent with ideas concerning its origin. One cannot rely on purely statistical arguments because among these small redshifts random motions and cosmological recession tends to smear possible non Dopplerian peaks which thus must be only weakly discernible.

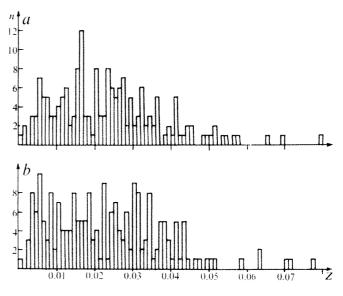

Fig. 2 Distribution of the redshifts of: a, s and sd objects combined: b, ds and d objects combined.

The value z=0.015-0.016 is half the value 0.03 and a quarter of 0.06. This might suggest a downward extension of Burbidge's relation<sup>3</sup>  $z=n\times0.061$ ,  $n=1, 2, 3, \ldots$ 

Figure 2a shows the redshift distribution for s and sd objects, and Fig. 2b for the classes ds and d. Evidently the peak originates mainly from the former ones, which is consistent with their more quasar-related nature.

If the peak is caused by intrinsic redshifts, the objects giving rise to it should be rather near, so that the cosmological redshift would not smooth it off. So it should originate chiefly from objects in the local supergalaxy. The dividing line on the celestial sphere given by Rubin et al. separates the low redshift ScI-galaxies (Region I) from the high redshift ones (Region II). Region II includes the central parts of the local supergalaxy. The shaded area in Fig. 1 represents the objects in and near Region I. Region II is chiefly responsible for the peak. Redshifts between z = 0.008 and z = 0.014 occur predominantly in Region I (ref. 7). From Fig. 1 it can be seen that at the peak and to the right of it the proportion of Region II redshifts increases.

Also in Arp's list<sup>17</sup> of interacting galaxy groups (five groups), six out of 16 hypothetical intrinsic redshifts (obtained by

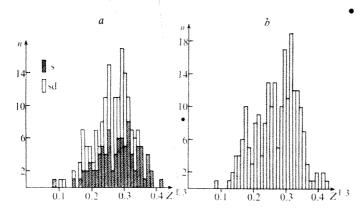

Fig. 3 Transformed  $(z \rightarrow z^{1/3})$  distribution of the redshifts of: a, s and sd objects; b, ds and d objects combined.

subtracting the redshifts of the primaries) would fall inside the peak z=0.015-0.016. Pecker et al. 18 have interpreted the redshift distribution of QSOs using the relation

$$z = aRT^3$$
,

where a is a constant, R the characteristic dimension of the QSO and T the temperature. The transformation  $z - z^{1/3}$  leads in the case of QSOs to a symmetric distribution around a plausible value of the temperature. It can be seen from Fig. 3 that the transformation  $z - z^{1/3}$  leads to a nearly symmetric distribution in the case of s and sd objects, but for ds and d objects the resulting distribution is less symmetrical. The small excess of numbers in the left hand side of the distribution of s and sd objects (Fig. 3a) comes from the peak at z = 0.005. This peak is seen also for the ds and d objects.

These data seem to support the view that compact and nearly compact Markaryan objects have anomalous redshifts. This is consistent with the general idea that anomalous redshifts are connected with compact objects.

### Missing mass around galaxies: morphological evidence

RECENTLY we have obtained convincing empirical indications on the considerable role of hidden matter in the dynamics of single and double galaxies<sup>1</sup>. It seems that this matter is concentrated around massive galaxies, forming their coronas. The total mass of galaxies is about one order of magnitude greater than the mass of their visible parts.

Massive galaxies like our Galaxy or the Andromeda galaxy, M31, are surrounded by clusters of small companion galaxies. Searches for new effects of galactic coronas have led us to the discovery of a correlation between the morphological types of companion galaxies and their distances from the parent galaxies. It seems that elliptical companions are strongly concentrated around the parent galaxies whereas non-elliptical (spiral and irregular) ones populate preferentially the peripheral regions.

To derive this dependence we have collected the data on the companions of our Galaxy and of three external spiral galaxies —M31, M81 and M101 (refs 2-7). The adopted distances of these galaxies are as follows: 0.69 Mpc, 3.25 Mpc, and 7.25 Mpc (G. Tammann, private communication). The joint distribution (luminosity as function of distance from the parent galaxy) of the companions of all the four galaxies considered is given in Fig. 1. The regions populated by elliptical and non-elliptical companions are very sharply separated and the line of segregation is well defined.

To understand the nature of the regularity discovered we draw attention to the fact that the segregation of companion galaxies is connected essentially with one property—the presence or absence of the interstellar gas in the companion. Spiral and irregular companions, both of them containing much interstellar gas, are located to the right of the segregation line elliptical companions, containing practically no gas, are situated to the left of this line. A simple estimate shows that the segregation mechanism does not reduce to the tidal interaction which is too weak to produce such radical effects. If we reject the possibility of specific very artificial conditions during the formation of galaxies, there evidently remains the suspicion that the only agent capable of producing the interaction of the galaxies studied is intergalactic matter surrounding massive galaxies.

Let us suppose that the corona of a massive galaxy contains much gas. Consider a companion galaxy having its own gas

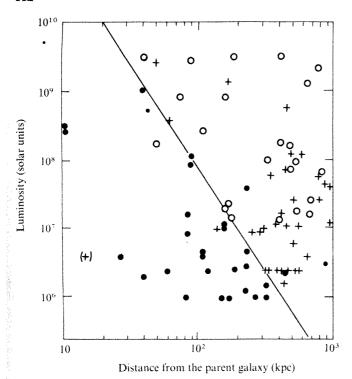

Fig. 1 The distribution (blue luminosity as function of distance from the parent galaxy) of the companions of our Galaxy and of three external galaxies: M31, M81 and M101. Elliptical companions populate the area to the left of the segregation line, non-elliptical companions to the right of this line. The presence of three spiral and irregular companions left of the segregation line is due to the projection effect; two elliptical companions right of the line have apparently more elongated orbits than other companion galaxies. •, Ellipticals; (), spirals; +, irregulars.

and moving through the coronal gas of the parent galaxy. The companion has a chance to preserve its gas only when the gravitational binding of this gas with the companion is stronger than the pressure of the coronal wind8. The gravitational binding energy can be expressed by the formula

$$U = -G\rho_g M_s R_s^{-1}, \tag{1}$$

where G is the gravitational constant,  $\rho_g$  the mean gas density of the companion galaxy,  $M_s$  and  $R_s$ —the mass and the characteristic radius of the companion. The expression for the pressure of the coronal wind is

$$p = \rho_c V^2, \tag{2}$$

where  $\rho_c$  is the density of the coronal gas near the perigalaxy of the companion orbit,  $V=(GM(R)R^{-1})^{1/2}$  is its orbital velocity and M(R) is the mass of the parent galaxy inside the companion orbit with the radius R. Since with an increasing distance R the density of the coronal gas decreases, the conditions for preserving the gas are the better the larger is R whereas in the inner regions of the corona we see only elliptical galaxies from which the gas is blown away by the coronal wind.

In order to estimate the mass of the gaseous corona,  $M_c$ , we have determined the density of the corona at various distances From the centre of the parent galaxy. This can be done, using the data on galaxies along the line of segregation, where the gravitational binding energy, |U|, is approximately equal to the pressure of the coronal wind, p.

According to Roberts9 the mass of dwarf irregular and spiral galaxies is proportional to their luminosity and the mean density of stars and gas is constant, and we have  $R_s \sim M_s^{1/3}$  and  $|U| \sim M_s^{3/3} \sim L_s^{2/3}$ . The segregation line between two morphological types of galaxies is a straight one  $L_s \sim R^{-3}$ , therefore  $|U| \sim R^{-2}$ . On the other hand, supposing a power law for the density of the corona

$$\rho_c \sim R^{-\alpha} \tag{3}$$

we obtain  $M(R) \sim R^{3-\alpha}$  and  $p \sim R^{2(1-\alpha)}$ . By comparing both expressions we get  $\alpha = 2$ .

The dependence  $\rho_c \sim R^{-2}$  leads us to the conclusion that outside the optically visible parts of the primary galaxy, where the density distribution is chiefly determined by the corona, the inner mass of the Galaxy,  $M(R) \sim R$  and the circular velocity  $V^2 \sim M(R)R^{-1}$  =const. This result agrees well with observational data on the circular velocity in the periphery of giant spiral galaxies10.

The derived density distribution agrees well with our previous results obtained from the dynamics of double galaxies1. For the distance  $R_0 = 15$  kpc we found for the coronal gas density  $\rho_0 = 2 \times 10^{-25}$  g cm<sup>-3</sup>. To estimate the total mass of the corona, the power law (3) cannot be integrated to infinity since the integral diverges. This shows that at large distances the density must decrease more rapidly than given by the law (3). On the other hand, we conclude from Fig. 1 that this law can be used until  $R^0 = 300$  kpc. Using this value of  $R^0$  as a limiting radius of the corona, we obtain for its mass

$$M_c \approx 4\pi \rho_0 R_0^2 R^0 \approx 2 \times 10^{12} \text{ solar masses}$$
 (4)

in good agreement with our dynamical estimate<sup>1</sup>. The mass found should be regarded as a lower limit of the mass of the corona since the adopted limiting radius Ro may be underestimated.

As noted by Oort11, the presence of large amounts of intergalactic gas is not surprising since the formation of galaxies is generally believed not to have been so efficient as to condense into stars all the diffuse matter in the Universe. Our data suggest that the intergalactic gas is not randomly distributed between galaxies, but is concentrated around massive galaxies, forming their coronas.

Dwarf elliptical companions of our Galaxy have been studied for stellar composition, which is almost identical to the oldest halo population stars<sup>4</sup>. This shows that star formation stopped soon after the formation of these galaxies. The space density of matter in the galaxies considered is small and under normal circumstances gas would be consumed at a very low rate12. A sudden cessation of star formation can be understood as an effect of the galactic corona, which blew the gas out from the nearby companions at an early stage of their history. But this points to the presence of the corona around the Galaxy just after its formation. At that early time the corona had to be gaseous.

#### An attempt to detect the effects of cosmic gamma-ray bursts in the lower ionosphere

DETECTION of gamma-ray bursts of cosmic origin by detectors onboard Vela, OGO, IMP-6 and OSO-7 satellites1-3 was one of the major surprises of observational astronomy recently. The bursts were observed over the energy range 7 keV to 1.5 MeV and were found to have time durations ranging from less than a second to about 80 s with integrated flux density between a few times  $10^{-6}$  and  $3 \times 10^{-4}$  erg cm<sup>-2</sup> for different events. From the 20 events that have been detected so far (from data accumulated over 5 yr) it seems that these events are distributed almost isotropically on the celestial sphere and occur at frequencies of about four to five each year, at the level of sensitivity of Vela satellites. In view of the absence of definitive positive associations with well known transient phenomena1,4 such as supernovae, galactic radio noise spikes, rapid atmospheric fluorescence increases, Cygnus X-3 radio flares or even with gravitational radiation events, continuous patrol for detecting these events through as many independent techniques as possible is very important to understand the nature of their origin.

So we have searched for the effects of these bursts on the VLF propagation characteristics in the D-region of the ionosphere; a technique<sup>5,6</sup> which earlier proved successful for the detection of X rays ( $\sim 1-10 \text{ keV}$ ) from sources such as Sco X-1. In short, the method consists of measuring the field strength of VLF propagation that shows absorption corresponding to the transit times of the X-ray emitting celestial bodies because of the resulting enhanced ionisation in the lower ionosphere. The effects of these bursts on the VLF propagation are investigated by examining the data on field strength variations recorded at Ahmedabad corresponding to 164 kHz transmission from Tashkent for several of the events recorded by the Vela satellites7. Further, since it is easier to delineate the ionospheric effects due to celestial photons in the absence of solar X rays, only those events that took place between the local times of 1900h and 0700h, corresponding to the geographical coordinates of the reflection point of these 164 kHz waves (32° N, 75° E) were chosen. Table 1 summarises the results of such a search for a number of bursts selected on the above criterion. The column on the observability of the event indicates whether the direction of the sky corresponding to the particular burst was within the visibility of the reflection point. Careful search of the recorded field strength data revealed no observable field strength variations associated with any of the above burst events. Figure 1 shows

Photograph of a typical record of the 164 kHz field strength variation recorded at Ahmedabad during March 28, 1972 event. This event had a total duration of ~ 65 s.

the relevant portion of a typical field strength record registered at Ahmedabad corresponding to the time of the occurence of the event dated March 28, 1971. The dotted line in the figure indicates the expected time profile7 of VLF field strength, if the X-ray burst event under consideration had an observable effect on the lower D-region of the ionosphere. The absence of an observable change in the field strength associated with the burst suggests that the X rays from this event did not have any significant influence on the ionisation of the D-region. Assuming that at least half of the uncertain cases should have been favourable from the observational standpoint, we conclude the results of the search for ionospheric effects of these events as negative.

Next, we estimated the electron production rates in the Dregion for a typical event such as of May 14, 1972, for which detailed spectral data8 are available above 7 keV. Since the atmospheric region between 90 and 70 km is most responsive to X rays between 1-10 keV (refs 6, 9), we have extrapolated the observed<sup>8</sup> power law number spectrum with an index of ~1.4 down to 1 keV for these calculations. Recent observations by Apollo 16 down to 2 keV justify such an extrapolation procedure (L. E. Peterson, private communication). The electron production rates for different heights are estimated for the two intensity peaks observed in the burst by the usual method using CIRA 1965 model of the atmosphere. The results are shown in Fig. 2 for the case of two zenith angles:  $\chi = 0^{\circ}$  and  $40^{\circ}$  together with that of Sco X-1 at  $\chi = 45^{\circ}$  for comparison Even though the electron production rates at the time of the second peak of the burst seem to be comparable with those from Sco X-1, the average production integrated over the duration of the burst of about 50 s is found to be at least a factor of two lower. One striking feature of the production profile is that the altitude at which the maximum rate of ionisation occurs for the burst is around 70 km compared with 85 km for Sco X4. At

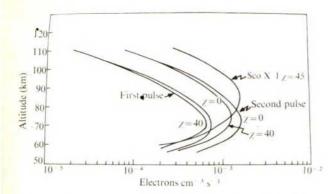

Fig. 2 Electron production rates as a function of altitude for the May 14, 1972, event. Also shown is the production rate due to the X rays from Sco X-1 corresponding to the zenith angle of 45°.

important consequence of such a profile is that the peak electron production rate for these types of bursts yields only low equilibrium electron densities because of the high values of recombination coefficients at the lower altitudes. The value of the recombination coefficient at 70 km is orders of magnitude higher than that at 85 km where X rays (~ 1-10 keV) from Sco X-1 have maximum influence and where consequently much higher equilibrium electron densities could be produced. Our estimates show that the electron density enhancement arising from this burst is insignificant at 70 km and is much less than 5% over the ambient value at 85 km. Because the burst under consideration is one of the strongest recorded so far, it is clear that the effects to be expected from the events listed in Table 1 should be many factors lower. We therefore conclude that for the type of bursts detected so far, the ionospheric effects are too weak to cause observable perturbations in the VLF propagation.

We thank Dr U. D. Desai of Goddard Space Flight Center, NASA, Maryland and Dr Hugh S. Hudson of the University of California at San Diego for providing lists of the gamma-ray burst events in advance of publication. We also thank Professor Laurence E. Peterson for comments. This research was carried out with funds from the Department of Space, Government of India.

#### No evidence for glacial origin of late Precambrian tilloids in Angola

KRÖNER and Correia1 claim that the mixtites in the Lower and Upper Tilloid Formations of the West Congo Sequence are "true tillites", although detailed study supports the idea that they originated as tilloids deposited by submarine mudflows in a geosyncline2. I question the validity of their arguments.

Mixtites which enclose striated clasts are not ipso facto tillites. Non-glacially striated stones occur in deposits unrelated to glaciation, and glaciclastic detritus may occur in non-glacial deposits. Clasts which have been abraded by nonglacial processes (including tectonism) can resemble glaciated clasts3.4. "Striated pebbles in mudflow deposits . . . have often been noted . . . and their similarity to glacially striated pebbles mentioned"<sup>4</sup>. If Kröner and Correia possess a diagnostic criterion which can provide an objective distinction between glacial and nonglacial striations on boulders, they would do well to state it. If their striated clasts are glacial-even today glaciers exist not far from the sea-that is still not evidence that the mixtites were deposited glacially, as till. (The West Congo geosyncline was at low to equatorial palaeolatitudes during tilloid accumulation5.) Glaciated stones in a delta would indicate glaciers in the hinterland but not the glacial deposition of delta sediments or the turbidites issuing from them. The striated boulders occur in a small area2. That restriction, which is unlike the situation for Pleistocene and older glacials, argues by itself against the extensive glaciation of land areas. To the north is a vastly larger area which lacks striated stones. Wagner and Wilhelm<sup>6</sup> examined over a thousand tilloid stones without discovering a single striation. The striated clasts occur near the south-eastern basin margin in Angola; the elevation of the source area may have been sufficient to cause local highland glaciation3.7.

The so-called "dropstones" are no such thing and have nothing to do with deposition of the tilloid formations; they are older. It is irrelevant to claim that a formation is glacigene because another, underlying, completely unrelated formation contains some small intraformational pebbles (which are not even erratics). Kröner and Correia found these clasts not in any tilloid formation but in the S3de formation (shales, siltstones, quartzites, carbonates and cherts) belonging to the Sansikwa Group. The Sansikwa and Lower Tilloid Formations are separated sharply by a disconformity/unconformity caused

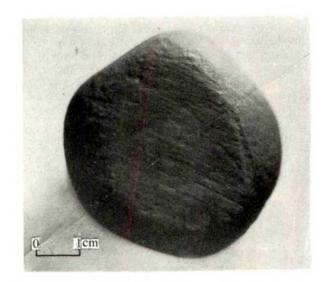

Fig. 1 Small, striated and faceted clast from the lower mixtite (M0), found west of Samba Cajú. The clast is also faceted on the back and these striations there have a markedly different direction from the front face.

by an erosional phase, and the tilloids carry eroded Sansikwa detritus as well as crystalline erratics. No dropstones appear in either the Lower or the Upper Tilloid Formation. The former encloses a thick mudstone level<sup>2</sup> which, if this formation were glacigene, could not fail to exhibit ice-rafted erratics. Kröner and Correia's Fig. 2 shows a minute pebble of intraformational siltstone in a subvertical position, only 8 mm long yet strongly deflecting silty laminae both underneath and above it: this is a compaction structure. A silt flake weighing only 0.25 g could not, dropping through water, have bored into bottom silt for a quarter of its length. Nor could it have been implanted subvertically: "in falling through even a few inches of water, pebbles rotate to place their maximum projection area (which is parallel to the long axes) approximately normal to the direction of fall"8. True dropstones, when small, lie parallel to the host rock lamination9, and are erratics. Nor is the pictured rock varve-like: it is similar to siltstone-shale alternations, such as the Tar Springs Sandstone, in which small silty pods also deflect and penetrate adjacent laminations (ref. 10, Plates 17C and 18C). Such current-transported intraclasts should not be confused with dropstones.

Graded bedding in tilloids and associated sandstones is frequent (though unknown from true tills or aquatills). Mudflows do enclose sandy lenses4. Internal stratification is rare, and not common, in tills; Boulton 11,12 has referred to flow tills which are mudflows.

The argument that turbidity currents could not have deposited the tilloids because they cannot carry coarse material, and that, consequently, these rocks must be glacial, makes no sense because this has never been claimed. Only mudflows have been envisaged, and their carrying capacity is well known2,3,

The tilloid formations are well stratified (the Lower Tilloid contains hundreds of tilloid beds). Their thickness varies from 0-500 m for the Lower Tilloid, and from 5 cm-200 m for the Upper Tilloid. Their greatest lateral extent in Angola is 100 km. Strong facies changes indicate lateral supply, with longitudinal input from geanticlines crossing the basin. That, and the absence of ice-rafting, the erosional bases which cut down 500 m into older strata and other evidence2, all argue against glaciomarine deposition.

Tilloid sedimentation was relatively deep marine, evidenced by widespread graded bedding (of normal type, not compositional layering) in tilloids and interbeds, and by the absence of shallow-water structures2,3. The tilloid formations are overlain by hundreds of metres of non-pebbly turbidites, and such thick, extensive, graded sequences do not occur on shelves. They pass up into shallow marine sediments with shallow-water structures. The laminated dolomite caps<sup>3</sup> which cover tilloids exhibit the characteristics of deep-water carbonates13, lacking shallowwater or lagoonal features. Quartz feldspar sandstone intercalations (with grading) occur in the tilloid formations, as well as among graded greywackes and mudstones in other formations, including flysch. Deep sea investigations show that clean sandstones can occur in a turbidite environment, and they have been reported from flysch troughs14-16.

The association of late Precambrian mixtites with limestone and dolomite is ironclad evidence against a glacial origin3. Experimental investigations and present day occurrences indicate that dolomite precipitation requires a minimum temperature of over 20° C. Recent and ancient precipitated carbonates and evaporites are concentrated at low latitudes<sup>17</sup>, where there are warm conditions. The absence of carbonate precipitates among Pleistocene, Permo-Carboniferous, Ordovician and Huronian glacials, confirms this.

Kröner and Correia's objections to nonglacial tilloid deposition are insubstantial; they did not dispute the main lines of evidence based on sedimentology and facies analysis2. The mudflow theory, which according to Kröner and Correia was "never accepted by any serious student", emerged from the detailed mapping of 77,000 km<sup>2</sup> of north-western Angola, covering 40% of the length of the West Congo geosyncline.

The results are available as map sheets with descriptive memoirs published by the Geological and Mining Service of Angola. No other late Precambrian mixtites in Africa, or indeed in the Southern Hemisphere, are as well documented. Serious and unserious students alike are free to interpret the assembled evidence as they will, for much remains to be learnt, but they should consider the whole of the evidence, not disregard essential parts of it.

DR KRÖNER REPLIES: Schermerhorn concludes that our evidence in favour of a glacial origin for the Angolan mixtites1 is insubstantial and unsound. During a field excursion in 1973 he failed to convince any of the participants of a mudflow origin for his tilloids. He also rejected a glacial origin for the late Precambrian Numees mixtite in South West Africa2-6. Here I shall correct some of the misinformation he presents.

We have not claimed that mixtites which enclose striated clasts are ipso facto tillites, but that the numerous scratched stones in the West Congo 'tilloids' showing striations in various directions, sometimes crossing each other, are additional evidence for glaciogenic deposition of the host rock. Nobody has yet proposed a mechanism by which a small clast (5 cm diameter) can first be faceted and then striated in different directions (Fig. 1) during mudflow deposition, and I believe I have the wide support of students of glaciogenic deposits in identifying such striae as glacial.

Striated clasts are not restricted to a small area but have been found both in Angola and in Zaire1. It is not surprising that none has yet been reported from northern Angola since outcrops are extremely poor there.

There is no evidence to suggest a low to equatorial palaeolatitude during mixtite deposition in the West Congo basin. neither the precise age of these rocks is known nor has their palaeomagnetism been investigated. Detailed work on the Numees mixtite (a possible equivalent of the lower Wes Congo mixtite) indicates, however, a high palaeolatitude?

Our small dropstone, which is only one of several found weighs 11.4 g and not 0.25 g. Schermerhorn's claim that pebble drop through water with their flat sides normal to the direction of fall is incorrect and disproved by countless examples of dropstones piercing with their sharp edges or corners through the underlying lamination<sup>3-5</sup>. Even small dropstones penetrate the host rock lamination in this fashion; that has been demonstrated to Schermerhorn on a visit to the Numees Formation.

Schermerhorn and Stanton<sup>8</sup> state that "deposition of the tilloids was thus a type of geosynclinal turbidite sedimentation" and "... a subaqueous mudflow ... even becomes a turbidity current". Also "The beds of quartzite (intercalated in mixtite-A.K.) must have arrived as turbidity currents".

The mixtites extend for more than 800 km in the West Congo Basin and no mechanism can explain this distribution satisfactorily by mudflow deposition.

The association of mixtites with carbonates is characteristic of most late Precambrian glaciogenic deposits9 but, contrary to Schermerhorn's belief, it is not evidence against glacial deposition. The Numees tillite3-6 and the Bthaat Ergil Group in, Mauretania<sup>10</sup>, to cite only two well documented examples are both undisputably related to ancient glaciation but, nevertheless, contain carbonate beds.

Dr Schermerhorn claims boldly but incorrectly that the Angolan mixtites are the best documented of all such sediments in Africa or in the Southern Hemisphere, though only one publication had appeared about them before ours. If it were true, the argument about their origin would long have been settled in favour of glacial deposition.

#### Work of fracture of natural cellulose

THE work of fracture (that is, the energy needed in order to form a fracture surface roughly at right angles to the grain direction) is, for timber, exceptionally high in relation to other mechanical properties and density. It compares well, on a weight basis, with that of ductile metals. Our tests on air dry (12% moisture content) pitchpine (Pseudotsuga taxifolia) for instance, give a mean value of  $0.92 \times 10^4$  J m<sup>-2</sup>. That is far higher than the energy needed to break the interatomic bonds in any given cross section of timber (which can hardly exceed 2 J m<sup>-2</sup>). It also seems to be noticeably higher than the energy that is likely to be absorbed by the fibre pull-out mechanisms which operate in conventional, artificial fibre composites<sup>1</sup>. There is reason therefore to suspect the existence of a special energy absorbing mechanism during fracture in trees and presumably, in other, plants.

Air dry timber has normally a macroscopic breaking strain in tension along the grain of about 1.0%, which is not very different from that of the cellulose fibrillae of which it is principally composed. Such a low breaking strain is not obviously compatible with the absorption of so much energy at fracture.

Cowdrey and Preston<sup>2</sup> have shown, however, that in the cell walls of timber the cellulose fibrillae are disposed in a preponderantly helical manner, making an angle which may vary between 6° and 30° in different cells but which always has the same sense in any one tree.

Page et al. have shown that when an individual cellulose cell is detached from its surroundings and pulled in tension, the walls buckle into the lumen in such a way that total longitudinal extensions of the cell of between 15% and 20% are possible. Page, however, was concerned with paper fibres and not with the fracture energy of timber.

We have made large ( $\sim 2$  mm diameter) model cellulose fibres by winding glass and carbon fibres into hollow helices with resin. When tested individually in tension, such tubes behave elastically up to a well defined yield point. Beyond that point the tube wall buckles and the equivalent of plastic yield takes place, enabling the tube to extend irreversibly by 10-20%, and thus to absorb a great deal of energy. We have made composite models resembling timber, by glueing together a number of parallel tubes of this type, and these exhibit experimental works of fracture up to about 40 × 104 J m<sup>-2</sup>, which may be higher than any value previously recorded for a non-metallic material.

We have observed that the fracture behaviour of timber, watched under the optical microscope, much resembles that of our fibre-composite models. The first irreversible event to be observed is the lateral separation of many of the cells in the immediate neighbourhood of the fracture (see ref. 4). That enables the walls of the cells in that region to buckle, and the cells themselves to elongate. Thus, although the elastic strain in the timber as a whole seldom much exceeds 1.0%, the cells close to the fracture surface typically extend 15-20% before breaking, absorbing much energy as they do so.

The adoption of a helical arrangement of reinforcing fibrillae naturally, involves some reduction in the maximum attainable value of longitudinal Young's Modulus. By calculation this reduction seems to be proportional to the square of the cosine of the helical fibre angle. That is equivalent to the loss of about 1% for a 6° helix, increasing to 25% for a 30° helix. Such a loss of stiffness may well be regarded as an acceptable price to pay for the acquisition of so much fracture toughness.

We acknowledge support from the Science Research Council for this research. A patent application is pending.

#### Imparting strength and toughness to brittle composites

HIGH strength and high toughness are usually mutually exclusive in composites which have brittle filaments in a brittle matrix. The high tensile strength characteristic of strong interfacial filament-matrix bonding can, however, be combined with the high fracture toughness of weak interfacial bonding if the filaments are arranged to have alternate sections of high and low shear stress (and low and high toughness). Such weak and strong areas can be achieved by appropriate intermittent

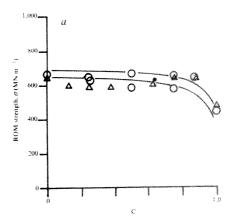

coating of the fibres. The strong regions ensure that the filament strength is picked up. Randomly positioned weak areas effectively blunt running cracks by the Cook–Gordon mechanism<sup>1</sup>, which in turn produces long pull-out lengths with an associated large contribution to toughness. Boron–epoxy composites of volume fraction 0.20–0.25 have been made in this way; they have fracture toughnesses of over 200 kJ m<sup>-2</sup>, and they retain rule of mixtures tensile strengths ( $\sim$ 650 MN m<sup>-2</sup>). At the volume fractions used, that apparently represents  $K_{\rm IC}$  values greater than 100 MN m<sup>-3/2</sup>.

When the interfacial bond between fibre and matrix is strong in composites which have brittle filaments and a brittle matrix, fracture is often caused by rapid matrix cracks which break through all filaments in their paths. The toughness of such composites is low because, in general, the critical transfer length associated with strong interfacial bonding is small, which limits the various components of the total toughness—the 'surfaces' component, Piggott-Fitz-Randolph stress redistribution and Cottrell-Kelly pull-out (see, for example, ref. 2). The critical length is given by  $l_{\rm crit} = \sigma_{\rm f} d/2\tau$ , where  $\sigma_{\rm f}$  is the filament strength, d the filament diameter, and  $\tau$  the interfacial shear strength.

A general increase of  $l_{\rm crit}$  by lowering the filament-matrix shear bond will increase the toughness, and a relationship between rule of mixtures (ROM) strength,  $\sigma$ , and total composite toughness, R, may be developed by recognising that in, general terms,  $R \propto l/\tau$ . Weak interfaces throughout the composite, however, reduce the tensile strength quite significantly. The question that presents itself is whether there are means by which the ROM tensile strength can be maintained along with high toughness values.

Marston<sup>3</sup> suggested that, providing there were 'sufficient' regions of high interfacial shear stress to ensure that the ROM strength was picked up, the rest of the composite could have quite weak interfacial bonds. Were such a composite to be laid up randomly with respect to weak and strong regions, both high strength and high toughness should be produced simultaneously. Then, if the lengths of the strongly bonded regions were greater than the critical length associated with the strong interfacial τ, the filament strength should be attained. At the same time, those weak interfaces situated randomly ahead of running cracks would serve to blunt the cracks by debonding.

Weakly and strongly bonded interfaces can be achieved by coating intermittently the filaments with some suitable substance before composite lay up. Experiments with silicon vacuum grease (SVG) and polyurethane varnish (PUV) coatings are described here; the uncoated regions have high interfacial shear stress and the coated regions are 'weak'. Tensile strength and toughness specimens were made from layers of intermittently bonded, epoxy composite tape, manufactured on a drum apparatus with a device for coating the filaments before lay up (A.G.A., unpublished). The tape (similar to Avco Rigidite, Prepreg tape) consisted of a 250 µm monolayer of B/W filaments in EPON 828 epoxy, backed, for ease of handling, on 760 mm wide nylon scrim cloth about 50 μm thick. The tensile strength specimens consisted of 2 layers of the tape, in 100 mm × 6 mm strips, with end tabs reinforced by additional layers. Most toughness measurements were made on flat sheet edge-crack specimens, similar to American Society for Testing and Materials 'compact tension' specimens in profile. These consisted of 10 layers of tape in panels  $76 \text{mm} \times 76 \text{mm}$ . To prevent the composite arms above the crack from shearing off under load, two outside layers of tape were arranged on each side of the specimens, with the filaments parallel to the crack. The central core of the specimen thus consisted of six unidirectional filaments perpendicular to the starter crack, where, within the limitations of the specimen and tape preparation method, the coated and uncoated layers occurred randomly, relative to each filament. Fracture toughness in the edge-crack specimens was measured for increments of crack area, using Gurney's sector area technique4.

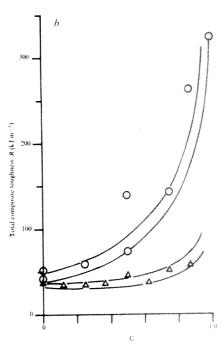

Fig. 1 Tensile strength (a) and edge-crack fracture toughness (b) plotted against the percentage coating, C.  $C = I_0/(l_c + I_{uc})$ ; where  $I_c$  is the coated length,  $I_{uc}$  the uncoated length, and  $(l_c + I_{uc})$  is the repeat distance of the coating pattern along the filaments.  $\bigcirc$ , Results with PUV coating;  $\triangle$ , results with SVG coating.

Tensile strength and edge-crack fracture toughness, for both SVG and PUV coatings, have been plotted against C, the 'percentage coating' (Fig. 1a, b). The tensile data remain at or about the ROM value until C becomes greater than 0.8. In the same range of C, the toughness with SVG coating, shows a modest increase over the initial (C=0) case. In contrast, the PUV coatings give marked improvements in toughness when the percentage of coating is increased (Fig. 1a, b): in the edge-crack specimens, with  $V_f=0.25$ , toughnesses of about  $100 \, \text{kJ m}^{-2}$  are produced for C=0.5, and values over 200 kJ m<sup>-2</sup> occur at large C.

Superimposed on the figures are the predictions of analyses for  $\sigma$  and R, details of which are to be presented elsewhere. Both coating materials maintain tensile strengths of the order of the ROM values up to large C, which suggests that both produce similar coated interfacial shear-strengths. Their effects on toughness are, however, different, which suggests that interfacial shear-strength may not be the controlling parameter for toughness. With PUV it seems that Cook-Gordon debonding takes place (average pull-out lengths of

 $l_{\rm crit}/4$  being augmented by additional debonding), but it is apparently absent in the case of SVG.

The Cook-Gordon mechanism itself seems to be only a small toughness sink, but the extra debond lengths markedly increase the pull-out contribution to toughness. The manner in which interfacial properties, other than shear strength, are affected by the coating procedure is therefore both interesting and important, because it is probably the 'toughness' of the interface that is of ultimate concern, rather than the 'strength'. Tensile debonding ahead of a crack, envisaged by Cook and Gordon, is Mode I fracture in the nomenclature of fracture mechanics; the shear debonding implicit in the Outwater–Murphy debonding analysis for toughness, is in the 'forward sliding' Mode II. Each mode has its own toughness, with explicit relationships with interfacial tensile and shear strengths, which are not obvious.

Further information on the intermittent bond concept is to be presented elsewhere.

# Effect of temperature on recombination luminescence and electron tunnelling

RECOMBINATION luminescence which occurs in alkaline glass after  $\gamma$  irradiation at 77 K, decreases in intensity when the glass is cooled. Between 60 K and 4 K the activation energy is probably about zero. This seems to be direct proof of a tunnelling mechanism.

Electron stabilisation occurs in deep intermolecular traps (2–3 eV) during low-temperature radiolysis of polar glasses. After γ irradiation, at 77 K, of aqueous alkaline glasses containing efficient electron scavengers (NO<sub>2</sub>-, NO<sub>3</sub>-, Fe(CN)<sub>6</sub><sup>3-</sup>), a long range electron transfer occurred, apparently by a tunnelling mechanism<sup>1,2</sup>. The observation and kinetic study of prolonged isothermal luminescence (ITL) in glassy organic matrices<sup>3,4</sup> and in alkaline glass<sup>5</sup> at 4 K and 77 K, which results from the recombination of trapped electrons (e<sup>-</sup><sub>t</sub>) and positive ions, confirms the validity of this mechanism; it also shows that the phenomenon is general in glassy materials.

Our aim was to study the temperature effect on recombination kinetics, using the ITL technique in the range between 77 K and 4 K, where electron tunnelling is apparently the predominant mechanism.

Sodium hydroxide glass (10 mol dm<sup>-3</sup>) containing phenol (0.03–0.3 mol dm<sup>-3</sup>) was used because ITL intensity is increased by the presence of phenol<sup>3</sup>. Irradiations were carried out at 77 K with a cobalt-60 source at a dose rate of 5 krad min<sup>-1</sup> for periods of 5–15 min. After recording the ITL decay for about 10 min, liquid helium was transferred into the cryostat, whilst monitoring of the luminescence continued.

Following  $\gamma$  irradiation of NaOH glass, whether pure or with phenol, at 4 K or 77 K, ITL can be observed for up to several hours. The kinetics of the decay, just as in the

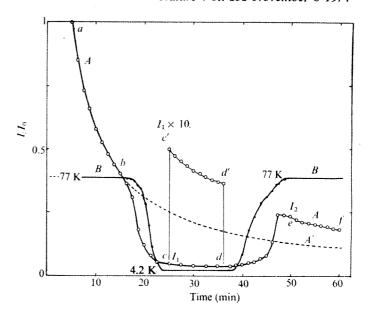

Fig. 1 Recombination luminescence in NaOH glass (10 mol dm<sup>-3</sup>) containing phenol (0.03 mol dm<sup>-3</sup>), irradiated with γ rays (dose: 50 krad) at 77 K. A, Luminescence intensity (relative units): sections ab and cd, ITL at 77 K and 4 K (c'd' enlarged 10 times); sections bc and de, luminescence intensity during cooling to 4 K and warm up to 77 K; section ef, ITL at 77 K after cooling and warm up cycle. A': extrapolation of the initial ITL decay at 77 K based on the linear plot of I/I₀ against time, according to equation (1). B, Temperatures corresponding to light intensities of A.

case of organic glasses<sup>4,6</sup>, can be described by the relationship

$$I_0/I = 1 + k(t - t_0) \tag{1}$$

in which  $I_0$  and I are ITL intensities at the beginning of the observation  $t_0$  and at time t; and k is a coefficient (with the dimension of a rate constant) depending on the duration of  $\gamma$  irradiation, but independent of dose and dose rate. Under identical experimental conditions, the kinetics observed at 4 K and 77 K coincide. The intensity of ITL after irradiation at 4 K is, however, approximately five times larger than after irradiation at 77 K.

Figure 1 shows the change of luminescence intensity with temperature in alkaline glass irradiated at 77 K. The decrease in temperature (Fig. 1, section bc) brings about a reduction of luminescence intensity by a factor of about five. Thus, the ITL intensity after irradiation at 4 K is actually about 25 times that after irradiation at 77 K and subsequent cooling to 4 K.

When the temperature is raised again (section de), the luminescence intensity increases and reaches a value higher than the normal ITL curve at 77 K (curve A'). The kinetics of ITL decay in the sections ab (77 K), cd (4 K) and ef (77 K) can all be represented linearly by equation (1). This indicates that the same recombination mechanism must be predominant under the experimental conditions of these luminescence decays.

This temperature effect is reproducible and can be repeated on the same luminescence decay curve, as long as there is sufficient light intensity.

Because the luminescence intensity at any moment is proportional to the reaction rate of recombination, it can be considered to be proportional to the rate constant when temperature is the only parameter which changes. Therefore, the fivefold decrease in luminescence intensity observed during cooling from 77 K to 4 K suggests an exceedingly low activation energy. In fact, there is practically no change between 60 K and 4 K.

From our thermoluminescence experiments (unpublished), the activation energy for charge recombination, ealculated by the initial rise method for the glow peak at 92 K, was found to be  $\approx$  7 kcalorie mol<sup>-1</sup> ( $\approx$  0.3 eV). This is an activation energy for a thermal detrapping process which is predominant at the glow peak. Its contribution decreases with decreasing temperature, and therefore the apparent activation energy calculated from the Arrhenius equation gradually decreases until it is practically zero below 60 K, when tunnelling seems to be the only process. Zero activation energy seems to be direct proof of a tunnelling mechanism in the decay of trapped electrons at sufficiently low temperatures.

These results confirm the general rules concerning the contribution of tunnelling to the rate constant of a chemical reaction\*. They show that below a certain temperature tunnelling plays the predominant role.

#### Volatilisation of terpenes from Salvia mellifera

WE have found that branches of Salvia mellifera, an aromatic shrub that grows in coastal southern California, produce sufficient quantities of terpenes to make a significant contribution to the atmospheric content of organic compounds. Our simultaneous qualitative and quantitative analyses of compounds volatilised by intact plants in controlled conditions represent an advance on previous measurements of organic compounds in the atmosphere surrounding plants1-3.

Salvia mellifera, the California black sage, is a shrub (1-2 m tall) distributed throughout the coastal regions of California from the San Francisco Bay area southward. In some immediate coastal regions it is the dominant plant species. Its herbaceous leaves, which are covered with glandular, terpene-containing trichomes, usually drop by the end of the long summer drought.

Net photosynthesis (under saturating light) and dark respiration were measured in an intact branch of a potted plant using a gas analysis system like that previously described4. The sample was contained within a cuvette where temperature and humidity were controlled. Photosynthetic and respiration rates were determined for various temperatures (Fig. 1).

The volatile constituents of the air emerging from the gas exchange cuvette were trapped in stainless steel loops which were packed with Pyrex wool and immersed in liquid nitrogen.

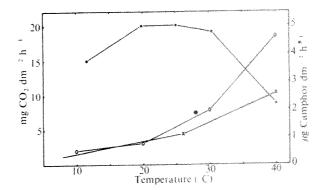

Fig. 1 Temperature curves for photosynthesis under saturating light (●), dark respiration (×) and camphor volatilisation (○ in S. mellifera.

A cryogenic pump maintained flow through the loops (1 I mine for 10 or 20 min). The organic volatiles were separated from the water which accompanied them and analysed qualitatively by gas chromatography-mass spectroscopy5. Gas chromatography alone was used for quantitative analyses. For convenience all quantitative measurements were based on camphor volatilised. The only other major volatile component was 1,8-cineol (23%), levels of which correlated closely with those of camphor (50%). Other terpene hydrocarbons (a-pinene, 8%; β-pinene, 4%; camphene, 4%; limonene, 3%; cymene, 2%; myrcene, 2%; β-phellandrene, 2% and γ-terpinene, 2%), were difficult to quantitate and were not measured.

Steady-state rates of terpene (camphor) volatilisation in the light and dark were determined by placing the plant in the chamber at constant temperature and humidity and monitoring the camphor produced until the rate of volatilisation was constant. Rates were directly proportional to leaf temperature (Fig. 1), and were the same in both light and dark.

Daily carbon gain and terpene loss by S. mellifera can be calculated using the temperature curve for the steady-state rate of terpene volatilisation and the gas exchange characteristics (Fig. 1) and the natural daily temperature regime of an area where the plant is dominant<sup>6</sup>. Figure 2 gives the temperature regime and calculated levels of terpene loss and gas exchange for April 1972 at a coastal site (Camp Pendleton, California) where S. mellifera is dominant. During this period the plant was physiologically active. The calculated rate of terpene volatilisation was 13.3  $\mu g\ dm^{-2}\ d^{-1}$ .

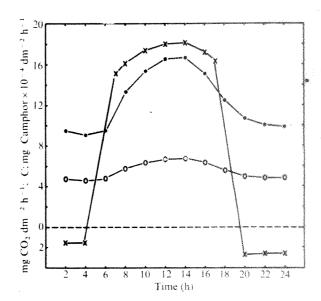

Fig. 2 Mean hourly temperatures for April 1972 at Camp Pendleton ( ) and calculated rates of CO2 exchange assuming saturating light during the light period (x) and camphor volatilisation (O) for S. mellifera at that site.

If 5.2 g of CO<sub>2</sub> is required to produce 1 g of camphor (18 mol CO<sub>1</sub>→6 mol 3-PGA→6 mol acetyl-CoA→2 mol mevalonic acide 1 mol camphor), the loss of photosynthate through camphor volatilisation was 0.03% in April. Since camphor represents 50% of the terpene pool in S. mellifera, the total loss of carbon by terpene volatilisation was 0.06% during April. This value is about two orders of magnitude below Went's predicted 5% loss of photosynthate as volatile terpenes from Artemisia tridentata1.

S. mellifera comprises 45.7% of the vegetation cover at the Camp Pendleton site. Based on the rate of volatilisation for April and a leaf area index of 2.6, 3.1 kg terpene km<sup>-2</sup> d-1 would have been released into the atmosphere from this site in April. This rate is one order of magnitude below that predicted for A. tridentata (50 kg km<sup>-2</sup> d<sup>-1</sup>) (ref. 1).

The measured rates of terpene volatilisation from intact branches of S. mellifera, which is highly aromatic, do not account for the high levels of atmospheric organics measured by Rasmussen and Went2 in the field. Their observations that levels increased immediately after fields were mowed and at times of maximum leaf drop in deciduous forests, but not with the appearance of new foliage in the spring, suggest that the source of volatiles was primarily decomposition or loss from dead cells, rather than volatilisation from intact plant material. Detailed analyses of field samples are required to determine the nature of volatile organics in the atmosphere; contrary to general assumption, many may not be terpenoid2.

Our study demonstrates significant terpene volatilisation from healthy, intact leaf material of S. mellifera. This loss of carbon represents a substantial metabolic cost which implies that it confers some benefit on the plant. Terpenes, especially camphor and 1,8-cineol, from S. mellifera have been suggested to act as phytotoxins in the ecosystem7. Quantitative data such as ours will allow a more comprehensive analysis of this proposal by indicating the contribution of Salvia populations to natural levels of terpenes in the ecosystem-levels at which the compounds must be active.

The terpene content of the leaves, which was measured as 31.5 mg dm<sup>-2</sup> by steam distillation, represents a large amount of potentially volatile material, which may lead to intervals of high atmospheric terpene levels at the time of leaf senescence. This might be especially important in the coastal sage communities of California, where leaf drop and high summer temperatures occur simultaneously.

Lead levels in the water of suburban Glasgow

THE association of soft water with increased plumbosolvency from domestic cold water systems1 has been shown by Beattie et al.2 to result in elevated levels of blood lead in persons resident in lead plumbed houses in soft water areas. This effect was particularly marked in people resident in houses supplied with cold water from lead lined storage tanks. Here we report a study carried out in an area of Glasgow whose residents were principally owner-occupiers of social classes one and two.

The houses studied were identified from the intersections of a grid placed over a 1 in 2,500 scale Ordnance Survey map. Each house was numbered and selected from a table of random numbers. This gave a total of 120 residences. After selection, householders were invited to take part in this survey of the lead status of their homes. The person first contacted was usually the person studied from each household. No person was included in the survey who had been resident in the house for less than 1 yr. Each participant had 10 ml venous blood withdrawn, heparinised and stored in ice. At the same time 250 ml bottles were left for a collection of the first morning flush of water from the cold water system.

Erythrocyte  $\delta$ -aminolaevulinic acid dehydratase (EC 4, 2, 1, 24) (ALA.D) the second enzyme of the haem biosynthetic pathway, which is often taken as a bioanalytical measure of lead exposure, was measured by the Commission of the European Communities Standard Method<sup>3</sup>. The results were expressed as µmol ALA utilised per ml RBC per min (Units). Blood and water lead levels were measured by flameless atomic absorption spectrophotometry (Table 1).

In the assessment of the results, the houses were arbitrarily divided into two groups; those less than 20 yr old (group A) and those greater than 20 yr old (group B). This division was chosen because before 1939 these houses were constructed with lead plumbing, and until 1967 lead 'link' pipes were used to connect the domestic copper system to the cast iron main. There were 50 houses in the survey, 12 in group A and 38 in group B. On the basis of this division, it was found that there was a highly significant difference in the water lead content of the two groups. The older group of houses (group B) had a mean water lead content of about 350 µg l<sup>-1</sup>, that is, ten times greater than the mean of 35  $\mu$ g l<sup>-1</sup> in group A. Indeed, in the latter group no water lead value was greater than 100 µg 1-1 (WHO upper acceptable limit), and 82% of the houses in group B were above this limit. Associated with this increase in water lead levels there was a significant 1.5-fold elevation of blood lead in the occupants of the older houses. There were, however, no significant differences in the age of resident examined, the duration of residence or of the sex ratio between the groups. When the water lead (PbW) and blood lead (PbB) levels were compared for all subjects in the study, a significant linear regression was found with regression coefficient r = 0.417 using the equation PbB = 0.018PbW+22.9.

Table 1 Lead in Glasgow water				
	Group A (< 20 yr)	Group B (> 20 yr)	Significance	
No. in group	12	38	Significance	
Mean age of house	13.5 ± 4.4	$42.6 \pm 4.2$	and prompty page.	
Time of residence	$8.8 \pm 5.3$	16.1 + 12.5	NS*	
Age of resident	$41.3 \pm 18.8$	$46.7 \pm 17.8$	NS	
Sex ratio (female:male)	2:1	29:9	produce.	
Water lead (µg 1 <sup>-1</sup> )	$34.6 \pm 29.5$	$353.1 \pm 255.6$	P < 0.001	
Blood lead (µg per 100 ml)	19.8± 8.4	$30.5 \pm 10.6$	P < 0.01	
δ-aminolaevulinic acid dehydratase (units)	27.8±13.2	22.3 ± 10.4	NS	
ALA.D Residence > 5 yr	20.4 - 12.0 (10)	10.0 : 5.1/20)	D . O 002	
(No. of subjects)	30.4 ± 12.9 (10)	18.9 ± 5.1 (30)	P<0.005	

<sup>\*</sup> Not significant

In the initial analysis, no significant difference was found between the groups for ALA.D activity. When subjects who had been resident in the houses for less than 5 yr were removed from the analysis, however, resulting in 10 subjects in group A houses and 30 in group B houses, a highly significant difference in ALA.D activities was observed. The difference was of the same order as the difference in blood lead values (1.5 times). As has been often previously shown, there was a highly significant negative exponential regression relationship between the blood lead and blood ALA.D with r = -0.46 using the equation ALA.D =  $34.5e^{-0.017 PbB}$ 

Of perhaps greater interest was the observation that for all residents in the survey there was a significant negative exponental regression relationship between erythrocyte ALA.D activities and water lead levels, using the equation ALA.D (=) 25.7e -0.0006 PbW

These results clearly demonstrate the possible environmental hazard from lead plumbing, especially in a soft water area such as Glasgow. It is difficult, indeed impossible, to determine the point at which low levels of lead ingestion may harm exposed persons. It is, however, significant that biochemical changes can be observed in ALA.D at blood lead levels as low as those found in this survey which represents the normal levels found in a large urban and suburban population. Remedial measures should, and indeed are, being taken in such areas of possible hazard, including the removal of lead plumbing and the 'hardening' of water with calcium and magnesium salts to lower the plumbosolvency of the water.

#### Feature processing in the perception and production of speech

It has long been argued that the perception and production of human speech are mediated by a common mechanism<sup>1-3</sup>; nonetheless, convincing evidence has not yet been obtained in favour of this view4. We discuss here, however, a series of experiments in perceptuo-motor adaptation that provide fairly direct evidence favouring the existence of such a mechanism. Our findings indicate that this mechanism processes information about individual phonetic features of consonants<sup>5-7</sup>, rather than processing these consonants as integral units.

Subjects were instructed to utter a given consonant + vowel syllable immediately after listening to repetitions of a selected adapting syllable. The utterances were analysed to determine whether a feature of the waveforms systematically varied as a function of perceptual adaptation. We concentrated on a single phonetic feature-voicing, in word-initial stop consonants. In English, voicing minimally distinguishes voiced from voiceless stop consonants-[b] from [p], [d] from [t], and [g] from [k]. This feature was chosen because: (a) it has an acoustic correlate that can be readily measured from real speech waveforms, (b) numerous data on perceptual adaptation have been obtained for this feature8-11, and (c) the feature serves to mark phonemic distinctions in virtually all natural languages12.

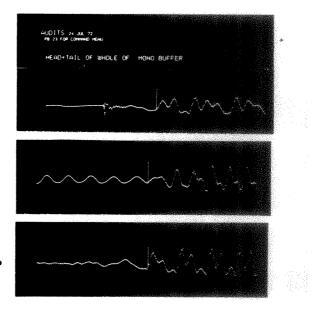

Fig. 1 Sample oscillographic displays of the utterances, illustrating the method used to analyse VOTs. The top display shows the initial segment of a [bi] utterance containing a short-lag VOT (voicing onset occurs shortly after the release burst of the consonant). The pointer T indicates the onset of the release burst, the vertical line to the right of T marks the onset of voicing, the time difference between the T pointer and the vertical line is displayed at the bottom right of the oscilloscope screen. For this utterance, the VOT is measured to be +11.6 ms. The middle display shows a segment of a prevoiced [bi] syllable (voicing onset precedes the release burst of the consonant). For prevoiced [bi]s, the pointer T (not shown in the display segment here) is set at the onset of voicing, while the vertical line cursor is aligned with the onset of the release burst. The time difference between the two markers is taken as the measure of VOT, in this case -86.6 ms (negative VOT values signify prevoicing). The bottom display shows a segment of aspiration and the onset of voicing for a [pi] utterance. The T pointer is set at the onset of the release burst (not shown in this display segment), and the vertical line cursor is moved to the position of voicing onset as in the case of the short-lag VOT [bi] utterances. The actual screen size is  $14 \times 13$  inches, and the vertical and horizontal display scales can be magnified to facilitate the marking procedure. The displays are taken from ref. 13

During speech production, voicing distinctions for word initial stop consonants can be signalled by voice onset time (VOT), a temporal relation between the release of oral closure and the onset of vocal cord vibration. Voiceless stops ([p] [t], and [k]) are normally produced with an onset of vocal convibration that lags behind the release of closure by more than 30 ms, whereas voiced stops ([b], [d], and [g]) are produced with an earlier onset of voicing. In this research the question of perceptuo-motor control was studied by analysing VOI values for a sample of approximately 5,000 consonant + vowe utterances, articulated under different conditions of perceptua adaptation.

Throughout the tests, three adapting syllables were used-[i], [pi], and [bi]. These syllables were five-formant synthetic speech patterns generated on a terminal analogue speech synthesiser (acoustic properties of these syllables are described elsewhere13). Subjects were tested individually in a sound insulated chamber. Forty adaptation trials were administered in blocks of 10 during an hour-long session, with a 5-min resi period between blocks. On each trial in a given block, the subjects were presented with 70 repetitions of a single adapting stimulus, with an inter-repetition interval of 350 ms. Subjects listened to the adapting syllable binaurally over headphones. They were instructed to hold their tongues firmly between their teeth and lips while listening and were told to minimise subvocalisation. After 70 repetitions of the adapting syllable were presented, subjects uttered a single CV syllable in a natural voice, as soon as possible (mean response latency < 1.5 s).

Each utterance was analysed oscillographically, aided by the AUDITS computer program <sup>14</sup>. A cursor was manipulated to mark the onset of the consonant release burst and the onset of voicing, and the time difference between the two marks was displayed on the oscilloscope screen to the nearest 100  $\mu$ s. The accuracy of each VOT measurement was estimated to be within  $\pm$  1 ms, except in the case of voiced consonants with VOTs near 0 ms, where the accuracy was reduced to about  $\pm$  3 ms. In all cases, accuracy was limited by our ability to specify the onset of voicing. Examples of the oscilloscope displays are shown in Fig. 1.

In the first experiments<sup>13</sup>, subjects were instructed to utter the syllable [pi] or [bi] on each block of trials after repetitive listening to [i], [pi], or [bi]. The results for the [pi] utterances showed a significant decline in VOT values after perceptual adaptation to [pi], compared with the VOT values obtained after adaptation to the isolated vowel [i] (P < 0.05). Thirteen of the 16 subjects showed this decline in VOT as a function of perceptual adaptation; the mean VOT shift was 5.6 ms. For the [bi] utterances, no systematic shift in VOT was obtained after perceptual adaptation to [bi], compared with VOTs obtained after adaptation to [i].

The asymmetry observed between the effects for [pi] and [bi] utterances was in accord with a number of additional facts. Whereas the distribution of the VOT values for the [pi] utterances was approximately Gaussian under all test conditions, and showed no highly elevated response peak, the distribution for the [bi] utterances was non-Gaussian and showed a very strong clustering of responses within the narrow range between 0 and 20 ms VOT. The presence of a well-defined target region for the VOT production of the [bi] utterances—a consequence of simple mechanical coupling by airflow<sup>15</sup>—may have accounted for their resistance to adaptation. Converging evidence of asymmetry between the processing of voiced and voiceless stops has been obtained in studies of perceptual adaptation<sup>8,9</sup>, speech production<sup>12,16,17</sup> and neonate perception<sup>18</sup>.

We were able to conclude that the perceptuo-motor adaptation effect for [pi] represented the fatiguing of a mechanism that mediates an aspect of both speech perception and production. In reaching this conclusion, we ruled out two alternative interpretations—perceptuo-motor compensation<sup>19</sup> and voluntary mimicry of the adapting syllable (see ref. 13 for details). Having demonstrated the existence of a perceptuo-motor effect, we conducted a second series of experiments to begin to determine the nature of the mechanism tapped by this procedure. We wanted to find out in particular whether the mechanism processes information about the stop consonants in toto or whether it

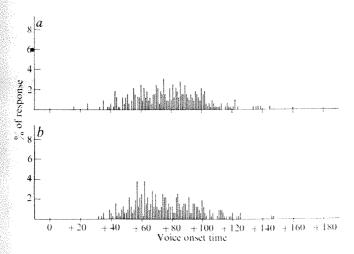

Fig. 2 Frequency distribution of the [ti] utterances for the group of 32 subjects after perceptual adaption to [i] (a) or [pi] (b). This display provides a good record of the range and distributional pattern of VOT values, although it does not easily reveal the small but significant shift in VOTs between the two test conditions.

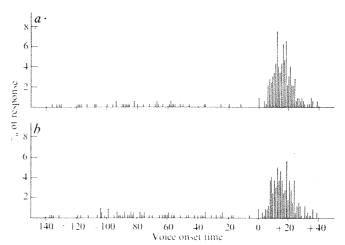

Fig. 3 Frequency distribution of the [di] utterances for the group of 32 subjects after perceptual adaption to [i] (a) a [bi] (b).

processes information about the individual phonetic features that comprise these consonants<sup>5-7</sup>.

In linguistic theory, the notion that consonants can be represented as bundles of distinctive features—features such as 'voicing' and 'place of articulation', to a first approximation—provides the chief means of accounting for relationships of phonetic similarity. Previous studies of perceptual adaptation<sup>8,9</sup> provided evidence that linguistic features may be processed during some stage of speech perception. The present aim was to determine whether these features are extracted at the level of processing which mediates both speech perception and production. We studied this question by examining the case in which both the adapting syllable and the selected utterance shared the relevant voicing property, but differed from each other in place of articulation.

In these experiments, subjects were presented the adapting stimuli [i], [pi] and [bi] as before. But now, the subjects' task was to utter the syllable [ti] or [di] after each group of 70 adapting repetitions. For each of the two CV utterance types, perceptual adaptation to [i] was counterbalanced across blocks of ten trials with perceptual adaptation to the CV syllable belonging to the same voicing category as the utterance.

The results of the experiments appear in Figs 2 and 3, where the VOT frequency distribution of the [ti] and [di] utterances are shown for each test condition. A total of 1,280 utterances was examined in these experiments (320 in each of the four experimental conditions). For [ti] utterances, a systematic decline in VOT was obtained after adaptation to [pi], compared with the VOT values obtained after adaptation with the isolated vowel (P < 0.01). Twenty-three of the 32 subjects showed this effect; the mean magnitude of effect was 3.2 ms. This average magnitude was about 2% larger than that obtained for [pi] utterances with the same subjects (based on data presented in ref. 13 and additional tests). The obtained effect for the voiceless stops thus seems to be entirely featurespecific. No systematic shift was obtained in the VOT values of the [di] utterances after adaptation to [bi]. The asymmetry observed between the effects for [ti] and [di] utterances corresponded to the asymmetry obtained earlier for [pi] and [bi] utterances. In both cases, perceptuo-motor effects were found for the voiceless stop consonants but not for their voiced counterparts. The corresponding difference in the distributional patterns for VOT held as well for the present data (see Figs 2 and 3).

The results for the [ti] utterances indicate that the stage of processing subserving both the perceptual and motor systems of speech performs at least one highly specialised function—namely, processing information about the voicing property of the consonant. Since the [pi] adapting syllable contained a consonant with a different place of articulation from the [ti] utterance, the perceptuo-motor effect cannot be attributed to a mechanism that processes consonants as indivisible units.

With the present experimental technique, in combination with direct study of certain laryngeal factors 20-22, we hope to further define properties of this perceptuo-motor component of the speech system.

#### Recognition of mother's voice in early infancy

CERTAIN characteristics of the human voice at normal levels have a great influence on the neonate<sup>1</sup>, and infants 1 month old can detect fine differences in speech-like sounds2,3. This enables a selective response to take place when the child meets adults. From birth, babies will turn towards the source of a sound, and this orientation to a voice helps them to learn about faces. We have also observed that infants are more interested in their mother's face when she is talking.

A mother's voice is a frequent and relatively unchanging event in the young infant's auditory world, and its early

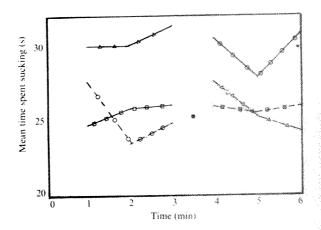

Fig. 1 Contrast effect for voice of mother (--) measured in mean time per minute spent stranger (sucking. △, Group I; ○, group II; □, group III (non-contingent). Interaction of voices and group scheduling was significant (P = < 0.05) as confirmed by analysis of variance, with repeated measure.

recognition has important consequences for the developing bond between mother and child. We report here a study which is the first designed to discover whether normal, 3-week-old infants from intact families can recognise their mother's voice. Successful recognition, we believe, is likely to aid communication.

We allowed the infants to control the auditory feedback they received (for instance, a mother's voice) by sucking on a teat to turn on the auditory stimulus. This technique, successfully employed by Siqueland et al.4 and Bruners may be used to find out what infants prefer to hear, (Operant conditioning of non-nutritive sucking has been demonstrated in neonates by Stern et al.5.) If a change in the way the infant sucks is shown to be dependent on whether it can hear the mother's voice or that of a stranger, it would indicate recognition of the mother's voice.

Babies 20-30 d old, and midway between feeds, were placed, when alert (Prechtl's Stage IV'), in an infant seat behind a screen. A blind teat placed in the mouth connected to a pressure transducer, and a light behind a transparent reading panel turned on when the infant sucked normally and alerted the mother to read. (A normal suck was 5 mm of water pressure.) Each baby heard mother's voice live and that of a female stranger equated for loudness, but saw no one. Strangers varied from baby to baby to avoid responses being due to the characteristics of one particular voice.

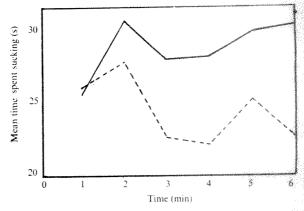

Fig. 2 Mean time spent sucking per minute during training for the contingent groups 1 and 2 combined (\_\_\_\_\_) and non-contingent group (\_\_\_\_\_). The groups and minutes non-contingent group (interaction as confirmed by analysis of variance was significant (P = < 0.05) as was the linear component of the interaction trend analysis (P = < 0.01).

Table 1 Babies discrimination between voices				
Schedule		Contingency training	Voice dis	crimination
Group 1 (n = 16 mean age 24 d, s.d. 2.6) Group 2 (n = 16, mean age 24 d, s.d. 2.6) Group 3 (n = 16, mean age 24 d, s.d. 2.2)	Base line sucking only Base line sucking only Base line sucking only	First stranger's voice contingent on sucking First stranger's voice contingent on sucking First stranger's voice controlled by non-contingent schedule	Mother's voice contingent on sucking Second stranger's voice contingent on sucking Mother's voice controlled by non-contingent schedule	Second stranger's voice contingent on sucking Mother's voice contingent on sucking Second stranger's voice controlled by non-contingent schedule 11–13 (inclusive)
Time (min)	0-1	2–7 (inclusive)	8–10 (inclusive)	11-13 (inclusive)

A non-contingent control with the same order of voice presentation as group 1 was achieved by equating total duration of feedback experienced by babies in group 1 on an individual subject basis. Schedules were generated by a computer program from the group data.

The procedure began with 1 min of sucking (baseline), and a 6 min training period followed during which the infant had a prolonged opportunity to learn the contingency between sucking and voice, and to integrate response and feedback. Data on discrimination between voices came from two further 3 min periods during which sucking produced the mother's and then the stranger's voice or vice versa (see Table 1).

The results for the voice presentation show that time spent sucking per minute and number of sucks per minute were greater (P = < 0.001 in both cases) when mother's voice was contingent on sucking. The duration of sucking for all groups is plotted in Fig. 1. No difference was recorded in the non-contingent group. Thus, the possibility of mother's voice increasing the arousal level of the infant would not account for the reported increase in sucking activity since the feedback-matching control effectively differentiates between stimulus and operant control of behaviour. Great variability in the duration of bursts of sucking in the first minute that mother's voice was available is consistent with the view that the mother's voice was initially responded to in the control group.

Non-nutritive or 'comfort' sucking typically has a rhythmic pattern in which bursts of sucking are regularly interspersed with pauses in activity. Babies could have achieved the increase in total time spent sucking when the mother's voice was available by a number of different strategies. In the event, for the mother's voice, mean burst length increased (P = < 0.025) and mean pause length shortened (P = < 0.01) as confirmed by analysis of variance. It is interesting that regulation of the sucking pattern was both systematic across contingent groups and an appropriate modification of behaviour if the mother's voice was to be found attractive.

Effects under contingent and non-contingent scheduling during the training period are plotted in Fig 2. Analysis indicates that infants were learning to produce a rewardthat of a complex auditory feedback as a result of their behaviour. Only future investigation can establish whether it is sensitivity to the contingencies inherent in the present task, or the processing of correlated information that is being demonstrated by these young infants.

Babies will expend greater effort, it seems, to hear a familiar voice. Our findings suggest that infants have already learnt some characteristics of their mother's voice, although we are not in a position to say which aspect they may be recognising. Nevertheless, successful discrimination of mother's voice is occurring before they are a month old.

#### Pathogenicity and cerato-ulmin production in Ceratocystis ulmi

THE recognition of aggressive strains of Ceratocystis ulmi associated with the epidemic of Dutch elm disease in Britain directed attention to the importance of variation in the pathogenicity of the causal fungus1.2. British workers3.4 have provided evidence of a correlation between pathogenicity and certain cultural characters such as colony appearance and growth rate. Here I describe a correlation between pathogenicity of certain strains of C. ulmi and the production of a metabolite named cerato-ulmin which, when introduced to elm seedlings, is capable of producing many of the symptoms of the disease.

Cerato-ulmin was previously described as microstructures<sup>6</sup> which are produced abundantly in liquid shake cultures of C. ulmi. It has unusual characteristics. As already reported5.6 these

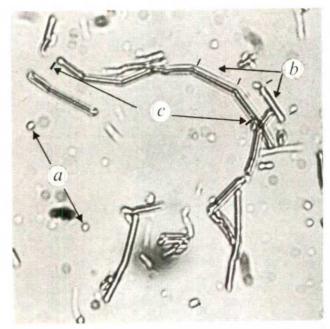

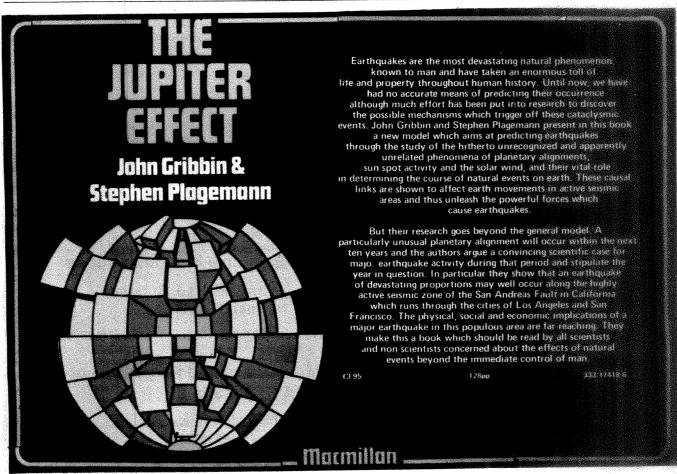

Fig. 1 Three unstable forms of cerato-ulmin in water as observed under the microscope. a, 'Unit' (a primary form); b, 'rod'; c, 'fibril' ( $\times$  256). ('Rod' and 'fibril' are assemblages of 'units.')

#### THE ALGAE

Second Edition

V. J. Chapman and D. J. Chapman

A completely rewritten and updated second edition of this successful student text. Information included ranges from a taxonomic survey of the principal divisions, classes and orders of the algae to a discussion of such topics as Ecology, Physiology and Bio-geography. Although the overlying approach of the book is general rather than specific few student texts are so comprehensive in their coverage.

#### EVOLUTION AND PLANTS OF THE PAST

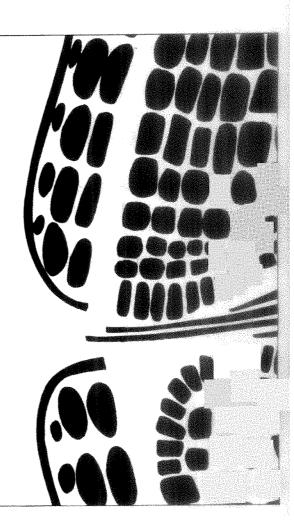

Harlan P. Banks

A wide-ranging discussion of a number of important aspects of palaeobotany. The basis of the approach is an examination of the way in which plants have developed from the earliest times, but in contrast with the more traditional approach, in which each group of plants is examined separately, this book looks at each geological period and treats its fossilflora as a whole. 'Dr. Banks' successful blend of scholarship and zest is manifest, and this book can be thoroughly recommended to students of palaeobotany'

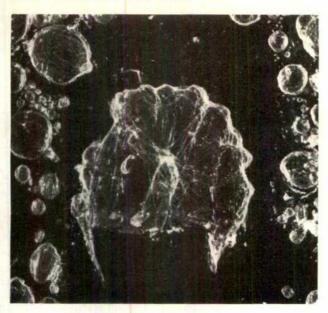

Fig. 2 By bubbling or vacuum effervescing (S.T., unpublished) rods and fibrils are forced on to the surface of the liquid as bubbles. When these accumulated bubbles burst, circular pieces of membrane, as shown here, remain floating on the liquid surface (× 30).

microstructures are of unstable form, and readily change from units' to 'rods' and 'fibrils' (Fig. 1). As 'units' the solution remains clear, but once 'rods' and 'fibrils' are formed the solution becomes milky in appearance. An additional assemblage of cerato-ulmin is 'membrane' (Fig. 2). After centrifugation, however, the fluid becomes clear. Such changes in morphology of cerato-ulmin in water indicate that it may be a liquid crystal, specifically a lyotropic liquid crystal. Cerato-ulmin seems to possess both carbohydrate and peptide moieties in its molecule.

Cerato-ulmin is certainly released into the culture medium but the actual production site has not yet been confirmed. When crushed spores which were repeatedly washed with water to remove cerato-ulmin from the spore surface were extracted, however, no cerato-ulmin has detected in the extract. It is therefore assumed that cerato-ulmin is produced extracellularly.

When five *Ceratocystis* species other than *C. ulmi* were cultured in the same conditions as those in which *C. ulmi* was grown to produce cerato-ulmin, no cerato-ulmin was detected. These species were *C. dryocoetidis* Kendr. and Moln., *C. fagacearum* (Bretz) Hunt, *C. major* (von Beyma) *C. Moreau*, *C. minor* (Hedge.) Hunt and *C. piceae* (Münch) Bakshi. Thus, cerato-ulmin seems to be a specific metabolite for *C. ulmi*.

Cerato-ulmin began to appear in liquid shake culture 3 d after inoculation, while active spore production was continuing and eventually reached 70% of the maximum level. Subsequently, the production of cerato-ulmin was rapidly accelerated but this accelerated production ceased 13 d after inoculation. Spore production was fluctuating at this time following peak production 5 d after inoculation. Beyond 13 d cerato-ulmin remained constant in spite of a levelling off of the spore number. This indicates that cerato-ulmin is a metabolite during active fungal development. In addition, even when a sharp reduction in spore numbers in the culture—probably indicative of autolysis—took place 22 d after inoculation, no change was detected in the level of cerato-ulmin. So cerato-ulmin is not considered an autolytic product of the fungus.

Cerato-ulmin causes white elm (*Ulmus americana* L.) seedlings to display symptoms similar to those produced by Dutch elm disease. A cerato-ulmin aqueous solution (120 mg ml<sup>-1</sup>) was continuously pressure injected (351.5 g cm<sup>-2</sup>) into the cuttings of 3-yr-old white elm seedlings in greenhouse conditions. An initiation of a substantial reduction in uptake appeared after 3 h; obvious drooping of leaves after 19 h; irreversible wilting and chlorosis on living leaves, after 43 h; and necrosis

on living leaves after 91 h. When the xylem was checked for brown discoloration at the end of the experiment (168 h after injections were begun), it was detected in all treated cuttings. No abnormal symptom was found in the control cuttings injected with distilled water however.

As cerato-ulmin seemed to be significant in disease development, the elucidation of the relationship between ceratoulmin production and the pathogenicity of C. ulmi strains was of great interest. There seems to be no correlation between spore production and either cerato-ulmin production or pathogenicity (Table 1). Production of cerato-ulmin was found to be either high or low according to the method of measuring used. On this basis, C. ulmi strains were divided into two obviously different groups: high production and low production. A striking fact is that all strains with high cerato-ulmin production were in the highly pathogenic group, while all strains with low cerato-ulmin production were in the weakly pathogenic group. This relationship seemed clear-cut with no overlap between the two groups on the basis of cerato-ulmin production and pathogenicity. It should be noted that, of the four British strains, two are highly pathogenic (aggressive) and two are weakly pathogenic (non-aggressive)3.4; these clearly separated in exactly the manner described above. Although there is variation in the production of cerato-ulmin in the high-production group of strains, it is not clear if intermediate production represents moderate pathogenicity of the strain because comparative data are insufficient for testing pathogenicity of those strains.

The ability of cerato-ulmin to produce symptoms of toxicity in white elm seedlings similar to those produced by Dutch elm disease suggests that cerato-ulmin could be responsible for disease symptom development in infected elm trees, if one assumes that the metabolite is produced in vivo. If this is the case, certain factors involved in cerato-ulmin production are inclined to induce symptom development. It is produced extracellularly and this ensures that there is good contact between cerato-ulmin and host tissues; because it is specific for C. ulmi it can direct specific symptom development, and its production during active fungal development is linked to its rapid production by the actively developing fungus within the host tissues. (Active development of the fungus is generally supposed to be dominant at the early stage of disease development.)

Together with the ability of cerato-ulmin to produce symptoms similar to those of Dutch elm disease, the correlation between cerato-ulmin production and pathogenicity indicates that differential production of cerato-ulmin is possibly responsible

for variations in pathogenicity among C. ulmi strains. On this basis, the production of cerato-ulmin might be a very useful criterion for fungal pathogenicity. Work is in progress to ascertain if it is applicable in a wider range of strains of C. ulmi than are presented here.

I thank Dr J. N. Gibbs and Dr G. F. Ouellette for cultures of their isolates, Dr E. S. Kondo for permission to use his data concerning the pathogenicity of C. ulmi strains in our collection, and Mr W. C. Richards for technical help.

#### Stomatal movements and ion fluxes within epidermis of Commelina communis L.

STOMATAL movements are brought about by differential changes in turgor pressure between guard cells and other epidermal cells1,2. The mechanism by which the turgor changes occur has been investigated for well over a century and a number of hypotheses have been proposed but none has been found to be completely satisfactory. Research in recent years has provided increasing evidence that active ion transport plays a major role in the stomatal mechanism3-6. It has been shown that, as stomata open, certain ions move into the guard cells and that this ion influx may be a dominant factor in raising the guard cell osmotic concentration. As a result, water enters the guard cells and brings about the opening movement. During closure of stomata the process seems to reverse whereby ions are lost by the guard cells. Cl- and K+ seem to be the major ions involved in the stomatal mechanism4.6-10

Humble and Raschke10 observed that in guard cells of Vicia faba the CI equivalents were considerably less than were needed to balance the K equivalents; a similar situation existed in the guard cells of Zea mays although the K-Cl imbalance was not nearly so great11.

Although Commelina communis has been used intensively for studies into stomatal mechanisms, assessment of the ion fluxes and charge balances involved have been neglected. Here we examine the fluxes of K, Cl, Ca and P between guard cells, subsidiary cells and epidermal cells of Commelina communis L. during stomatal movements. The results are discussed in relation to the K-Cl balance within the cell types in a closed and open stomatal apparatus.

Leaves from C. communis grown in the greenhouse in a peat-vermiculite mix supplemented with a complete fertiliser were used in the experiments. To obtain open stomata, the youngest, fully expanded leaves were floated on deionised water, abaxial surface downwards and illuminated from above for at least 3 h. Closed stomata were obtained by placing potted

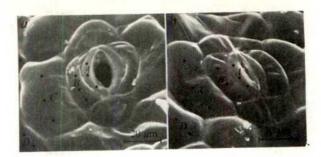

Fig. 1 Scanning electron micrographs of, a, an open and, b, a closed stoma of C. communis showing the approximate positions of point analyses in, A, a guard cell; B, an inner lateral subsidiary cell; C, an outer lateral subsidiary cell; and, D, epidermal cell.

plants in a darkened cupboard for 3 h. Before the epidermis was detached the leaves were examined under a microscope at low power (x 100) to ensure that the stomata were open or closed. The abaxial epidermal strips, cuticle side uppermost, were placed on to carbon disks and rapidly frozen in liquid nitrogen. The epidermis, still attached to the carbon disks, was then freeze dried for not less than 60 min at  $-40^{\circ}$  C under a vacuum of 0.05 mm mercury. After coating with carbon (approximately 100 µm thick) a dispersive-type analysis for the elements was made in the various cells of the epidermis (Fig. 1) using a scanning electron microscope with a solid-state X-ray detector attachment (Acton Ms-64 electron probe). The microscope was operated at 18 kV accelerating voltage with a sample current of approximately 100 nA. The take-off angle was 18°.

After obtaining secondary electron images of the stomata (Fig. 1), spot analyses (100 s counts with a spot size of 1 μm) were made at three positions (Fig. 1) in each of the following cells; guard cell, inner lateral subsidiary cell, outer lateral subsidiary cell and epidermal cell. This procedure was repeated three times for an open stoma (13 µm aperture) (Fig. 1a) and a closed or nearly closed stoma (>1 µm aperture) (Fig. 1b). Potassium X-ray intensity slowly decreased with time due to volatilisation and so care was taken to initiate counting at the same relative time on each point. Thus, the error inherent in an analysis was comparable in each measurement.

Solid state X-ray spectrometers (used in this study) lack the energy resolution of the crystal spectrometers of the electron-microprobe analysers and although they measure through the whole spectrum simultaneously there is some interference between elements being measured. In efforts to minimise this the specimens were coated with carbon rather than metals which are normally used to obtain secondary electron images.

Both Ca and P are considered to be relatively immobile12, a contention supported in these studies by the relatively constant

Table 1 Levels of K, Cl and Ca based against cell P levels and the K-Cl ratios in different cells of the epidermis of C. communis when the stomata were open (13 µm) and virtually closed (>1 µm)

Ratio	Guard cell	subsidiary cell	Outer lateral subsidiary cell	Epidermal cell
		Open stomata	L	2 20 1 0 40
K-CI	$1.29 \pm 0.16$	$1.65 \pm 0.44$	$1.99 \pm 0.72$	$2.20 \pm 0.60$
Ca-P	$1.83 \pm 0.36$	$1.92 \pm 0.38$		
K-P	$5.37 \pm 0.83$	$2.37 \pm 0.38$	$2.43 \pm 0.71$	$3.04 \pm 0.79$
CI-P	$4.22 \pm 0.85$	$1.47 \pm 0.21$	$1.24 \pm 0.10$	$1.42 \pm 0.28$
CII		Closed stomat	a	
K-Cl	$1.88 \pm 0.15$	$1.97 \pm 0.33$	$2.47 \pm 0.50$	$2.99 \pm 0.44$
Ca-P		$1.93 \pm 0.59$	-	
K-P	$3.21 \pm 0.41$		$3.75 \pm 0.67$	$4.03 \pm 0.56$
CI-P	$1.70 \pm 0.18$	$1.43 \pm 0.15$		$1.38 \pm 0.27$

Each figure represents the mean of nine determinations with its accompanying standard deviation.

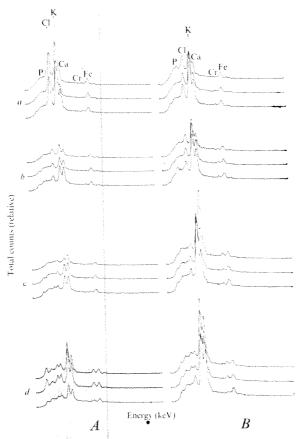

Fig. 2 Representative X-ray spectra of a microprobe analysis (three points per cell) of, a, a guard cell; b, an inner lateral subsidiary cell; c, an outer lateral subsidiary cell; and, c, an epidermal cell of C. communis with an open stoma, A, and a closed stoma, B. The Cr and Fe peaks are from the pole piece of the microscope.

Ca-P values observed in guard cells and inner lateral subsidiary cells when stomata were open and closed (Table 1). Ca-P ratios for the outer lateral subsidiary cells and epidermal cells could not be obtained because these cells contain large crystals of calcium oxalate and frequently the electron beam would hit a crystal and send the counts off scale (Fig. 2c, column B). Since the sample current varied slightly for specimens with open and closed stomata, peak heights for each of the elements could not be directly compared. Therefore, the K and Cl peaks were based against the P peaks which were considered constant from cell to cell. By expressing the K and Cl levels against P (which acts as a 'standard') errors which would be caused by the increase in guard cell volume when stomata are open are also largely eradicated.

Figure 2 shows representative X-ray spectra of the different cell types associated with an open stoma, A, and a closed stoma, B. A qualitative picture of the change in the levels of the different elements in each of the cell types associated with the open and closed stomata can be deduced from the peak heights.

Table 1 bases the peak heights of the elements against the P 'standard' enabling a more quantitative picture of the levels of the various elements within the cell types to be obtained. Highest levels of K were observed in the guard cell of the open stoma with least in the neighbouring inner and outer lateral subsidiary cells. In the case of the virtually closed stoma, K levels in the guard cell decreased relative to the open stoma while levels in the inner lateral subsidiary cell, and particularly the outer lateral subsidiary cell and epidermal cell, increased. Except for the guard cell of the open stoma which possessed the highest Cl levels, Cl levels were similar in all the cell types regardless of whether the stomata were open or closed. Thus, when a stoma of C. communis of aperture 13 µm closes to about 1 µm in response to darkness, K moves out of the guard

cell setting up a flux across to the epidermal cell. The revers flux would occur upon opening. It would be presumed that Cl follows a route similar to that of K although, in thes studies. Cl levels were not observed to increase in subsidiar and epidermal cells upon stomatal closure. Possibly Cl move rapidly to other epidermal and/or mesophyll cells and does no accumulate in the subsidiary cells as K does. Only when for reach epidermal cells are they able to enter mesophyll cell directly since the sub-stomatal cavity underfies guard an subsidiary cells.

Such a pathway for K (and possibly Cl) movement pose questions regarding the position(s) of the ion pump(s). pump system presumably could be located in the guard ce plasmalemma which would maintain K gradients between it an the adjoining cells. Alternatively, a pump could be locate in each cell type. A further consideration is whether the ior move between the cells through plasmodesmata and/or throug the cell-free space.

Thus, the ion fluxes in C. communis do not seem to b similar to those in maize in which there is a movement of I and Cl between a pair of subsidiary cells and guard cells durin stomatal movements11. The grasses in general, in fact, seem t possess a K shuttle between guard cells and subsidiary cell during stomatal movements13.

K-Cl ratios in the different cells types increased in the orde of guard cell < inner lateral subsidiary cell < outer latera subsidiary cell < epidermal cell. This order was maintaine regardless of whether the stoma was open or closed (Table 1 Thus, there was a greater inbalance of the two ions in epiderina cells. This inbalance of K-Cl also tended to be greatest in a the cells associated with the closed stoma. If organic aci anions bring about electrochemical neutrality balancing th excess K, as Humble and Raschke10 have suggested in epiderma cells, then it would be expected that the production of suc anions must be even greater in epidermal cells. Evidence so to does not support this contention, however, since enzyme involved in the production of malate and certain other organi acids seem to predominate in the guard cells rather than the epidermal cells14. Presumably, however, organic acid flux from guard cells to the epidermal cells could overcome th

We thank Drs J. Brown and J. Johnson of Georgia Technica University for their help in the operation of the microprobe.

#### Carbohydrate-binding protein from Polysphondylium pallidum implicated in intercellular adhesion

INTERCELLULAR adhesion is generally believed to be mediated by specific macromolecular components on the surface of the interacting cells. Soluble factors which may play a part in this process have been identified in a number of systems1-8. We have already described a developmentally-regulated carbohydrate binding protein 10,11 from the cellular slime mould Dictyostelium discoideum that appears in differentiating amoebae in close correlation with the development of cohesiveness10. This protein is assayed by its erythrocyte agglutination activity that can be inhibited by specific sugars. We now report the isolation of a similar protein from another cellular slime mould, Polysphondylium pallidum that seems to mediate specific cellular adhesion as judged from the following findings: (1) it is present on the cell surface; (2) it is present when the cells are differentiated to a cohesive state but absent when the cells are not cohesive; (3) addition of the purified protein promotes cell cohesion; (4) sugars which react with the active site of the molecule block cell cohesion produced either by the added purified substance or by the endogenous substance present on cohesive cells; (5) the precise reactivities of the protein from P. pallidum differ from the protein from D. discoideum, which correlates with the segregation of these cells in mixed culture.

P. pallidum, like the other cellular slime moulds, exhibits two distinct phases in its life cycle<sup>12-14</sup>: a non-social vegetative phase and a cohesive phase, initiated by starvation. To generate vegetative and cohesive cells, 105 spores of P. pallidum WS-320 in association with pregrown Aerobacter aerogenes were inoculated on to standard medium (SM) agar plates<sup>15</sup> (100 mm diameter) and incubated in a moist atmosphere at 22° C in the dark. Cells in the growth phase (or not far from it) were collected from plates after 63 h of incubation when their density was fairly low (7 × 10<sup>7</sup> per plate), washed in cold H<sub>2</sub>O and separated from bacteria by centrifugation. The amoebae were differentiated16 into the aggregation-competent state by suspension (10<sup>7</sup> ml<sup>-1</sup>) and reciprocal shaking in 0.0167 M Na<sub>2</sub>HPO<sub>4</sub>-KH<sub>2</sub>PO<sub>4</sub>, pH6.0. At intervals cells were removed for assay of cohesiveness and to be extracted for erythrocyte agglutination activity (Fig. 1). The cohesiveness assay, modified from one described previously10, measures the size of clumps formed from single cells passively brought into contact by roller-tube agitation. It has been demonstrated 20,21 for D. discoideum that the size of free suspension agglutinates formed from single cells in the presence of EDTA correlates with the ability of the cells to form morphogenic contacts.

**Table** Sugar effects on agglutination of erythrocytes by discoidin or *P. pallidum* agglutinin

SERVICE STATE OF THE PARTY OF T		

Purified P. pallidum agglutinin and discoidin<sup>11</sup> were assayed for agglutination activity as described in Fig. 1 in the presence of a eries of concentrations of sugars to determine the sugar concentration required to inhibit agglutination activity by 50%.

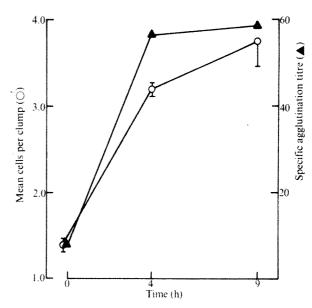

Fig. 1 Agglutinin activity (▲) and cohesiveness (○) during development of *P. pallidum* in suspension culture. Cells maintained on SM plates<sup>15</sup> with bacteria for 63 h were washed free of bacteria and inoculated in suspension medium without bacteria<sup>16</sup>. Aliquots of differentiating cells were removed for assay at the times indicated. For the agglutination activity assay extracts were prepared by sonicating  $3 \times 10^8$  cells (Bronwill Sonifer with needle probe; four bursts of 25 s each at intensity 50) in 3 ml of 75 mM NaCl, 75 mM KCl, 1 mM EDTA, 15 mM Tris-HCl (pH 7.3)<sup>17</sup> containing 0.3 M D-galactose. Extracts were centrifuged at 150,000g for 45 min (4° C). Supernatants, after extensive dialysis against 75 mM NaCl, 75 mM Na<sub>2</sub>HPO<sub>4</sub>-KH<sub>2</sub>PO<sub>4</sub> (pH 7.2) (PBS) were assayed with formalinised human red blood cells<sup>18</sup> (FHRBC). Assays were performed in Microtiter V plates (Cooke Engineering) using serial twofold dilutions of the extract. Each well contained 25 µl of saline (0.15 M NaCl) plus 25  $\mu$ l of extract diluted in PBS to which 25  $\mu$ l of a 2.5% (v/v) suspension of FHRBC in PBS was added. The patterns were read after 1.5 h. Titre was expressed as the reciprocal of the highest dilution giving positive agglutination. Specific agglutination activity was expressed as titre divided by protein concentration. Protein concentration was determined by the method of Lowry et al.19 with bovine serum albumin as a standard. For the cohesiveness assay the procedure was as follows: (1) Cells collected from the suspension culture were washed in water (4° C) and suspended in EDTA-phosphate buffer (16.7 mM Na<sub>2</sub>HPO<sub>4</sub>-KH<sub>2</sub>PO<sub>4</sub>, 10 mM EDTA (pH 6.2)) as modified from Gerisch<sup>20</sup>. (2) The suspension was dispersed into single cells by repeated pipetting through a fine-tipped pipette and was adjusted to a concentration of  $5 \times 10^5$  cells ml<sup>-1</sup>. 1 ml of this suspension was diluted 50-fold in EDTA-phosphate buffer and counted with Coulter counter (Model ZB-I) using a 200 µm aperture with 1/aperture current at 1/16, 1/amplitude at 1/8 and the lower and upper thresholds set at 20 and  $\infty$ . (3) 5 ml of the cell suspension was added to a  $17 \times 150$  mm glass test tube. The tube was rolled about its long axis at 20 r.p.m. for 30 min (23° C). (4) The contents of the tube were diluted 20-fold in EDTA-phosphate buffer and counted in the Coulter counter at the above settings. With coincidence corrections, the ratio of the total number of particles before and after rolling was computed. This ratio is the mean number of cells per clump and is taken as an index of cell cohesiveness. The standard error of the mean for three separate determinations is shown.

Cohesiveness of cells and specific agglutination activity in cell extracts increased in parallel after separation from bacteria (Fig. 1). In subsequent experiments, we found that synchronous growth-phase cells grown in suspension with bacteria the under conditions in which all cells had equal and ample bacterial food, contained no detectable agglutination activity. Thus agglutination activity was absent in vegetative cells, but appeared in food-deprived, differentiating cells.

To purify agglutinin we cultured cells on SM plates for 90 h in the dark. Under these conditions the cells become cohesive but do not develop beyond broad, loose aggregates. We sonicated the cells in 0.15 M NaCl, 0.3 M galactose, adsorbed the dialysed supernatant with formalinised erythrocytes and (Continued on page 149)

# Book Revieu Supplement

THE prefix 'para—', says the OED, means 'beside, beyond, wrong, irregular''. Excellent—just right for the terms 'parascientist' and 'parathinker'.

Tact prevents my naming presentday parascientists and parathinkers: but anyone can see that some of them at least must be identified by the field of intellectual endeavour in which they oprate, that is to say in interpreting what I shall call the 'it-makes-you-think-don't-it?' type of seemingly natural occurrence such as being given one's grandmother's maiden name by a clairvoyant, seeing Uri Geller bend teaspoons, or guessing (beyond statistical prediction) what the next card but one is going to be that somebody turns up in the next room. If the last of the three actually does happen to hold water from a statistical point of view, it remains egregiously boring and useless: it doesn't lead to anything. And the first two are drawn from a field of human activity that is, alas, far too wide-open to illusion, charlatanry and

But the serious point I want to make is something other, something which underlines my scorn for parascientists and parathinkers. It's this. So much of the interpreting, let alone the theorising, of parascientists and parathinkers is based on seemingly natural occurrences which either cannot be fully corroborated according to the rules of evidence, or cannot be properly repeated according to the rules of experiment-or, of course, both. Yet this is not to say that to me the most striking thing about parascientists and parathinkers is their being beside, beyond, and so on; lots of scientists and thinkers have been all of those. (Think of Newton on numerology.) What to me seems the most striking thing about them is what makes them lurable into the beyond, beside, irregular and wrong: namely an astonishing credulity. The critical link between 'it-makes-youthink' and 'there-must-be-something-in-

### All parasense

William Cooper

Aldous Huxley: A Biography Vol. 2: 1939–1963. By Sybille Bedford. Pp. xii+378+15 photographs. (Chatto and Windus, in association with Collins: London, 1974.) £4.50.

Aldous Huxley. A portrait by Alfred Wolmark, drawn in 1928. (National Portrait Gallery)

it' seems to me indefensibly weak, if not totally absent. I don't understand it: they include some very clever men. Here speaks one of them:

"Elinor Bond doing telepathic guessing ... Frances Farrelly, with her diagnostic machine ... Harry, the Dutch sculptor, who goes into trances in the Faraday cages and produces automatic scripts in Egyptian hieroglyphics; Narodny, the cockroach man, preparing experiments to test the effects of human telephathy on insects ... It was all very lively and amusing and, I really think, promising ..."

All very lively and amusing is for him to say, naturally. Promising—we can have an opinion on that. The only think it surely promises is more of the same nonsense. The speaker is Aldou Huxley.

Now we all have our off-moment and the quotation, which comes from the second volume of Sybille Bedford biography of Aldous, may not be er tirely fair. But it is not entirely unfair The part played in the second half c Aldous's life by-shall we call it?parasense, in whatever degree of light heartedness or seriousness, is too grea to allow that he be absolved from th charge of astonishing credulity. It i clear that he, being one of the mos intelligent of men, was singularly fre from pomposity, ill-will and aggressive ness: all his friends loved him as self lessly thoughtful and harmoniou almost to the point of saintliness. Th condition of men in the twentiet century, Isaiah Berlin observes, wa the single theme that dominated hi late years. And beyond warnings to mankind-first of nuclear holocaus and then of ecological catastrophe-Aldous's message for each of us, per sonally, delivered with a most taking humility and amused down-to-earth ness was: Try and be a little kinder to each other. Hard to resist, I must say. True, there was something remote about him: as everybody has pointed out, he scarcely noticed that his first wife, Maria, was dying of cancer. (Or the other hand he too died of cancer with great dignity.) Yet . . . why did he allow himself to be so credulous about paranormal occurrences, about 'mind-changing' drugs and the like? The only person to give any sort of answer is Charles Snow, who suggests "just one touch of immodesty. . he kept his mind open beyond the limits of openness, could he perhaps happen on something earth-shaking, altogether outside the common run of life? And enjoy announcing it to an astonished world? Like a more dramatic T. H. Huxley about something more exciting than Darwin's

Theory?" It's hard to come up with a more likely answer. Poor Aldous: it never came off; it never could.

So Mrs Bedford arouses our compassion. Over my regard for her as a biographer I shot my bolt when reviewing Volume 1 in this journal. I see myself quoted on the dustjacket of Volume 2: "Mrs Bedford has great literary talent and through everythink she writes shines a sympathetic intelligence-not to say an admirably unforced professionalism as well". I stick to that. Over a final verdict on the biography I naturally insisted on waiting until the end. The doubts I had at that time have not really been resolved now that I have read the second volume. I noticed that the book has the flavour of close, cosy, penetrating gossip: all well and good-but I feel that in the end it becomes too much of a good thing. There are too many gossippy letters from Maria, too many long quotations from other people's letters. And for my taste there is too much detail-Joe Blodgett'ish, American academic, research detailabout Aldous's incessant, restless lecturing tours. (Did he really have to travel so much, and to live in southern California, in order to make a living and maintain his health? Such a life was particularly bad for him; he ought to have stayed put, among more stableminded men of his own intellectual stature, in a less fatuous culture.)

Finally, I get a recurrent feeling that Mrs Bedford, who knew Aldous well and was a close friend, is somehow in this volume shielding him, protecting him from criticism. It's wholly understandable, and it's permissible for part of the time; but there's another part of the time when a biographer must come clean, and cold—or so it seems to me. All the same, Mrs Bedford has written a remarkable and valuable book

# Science from the beginning

Early Physics and Astronomy: A Historical Introduction. (History of Science Library.) By O. Pedersen and M. Pihl. Pp.413. (Macdonald: London; American Elsevier: New York, August 1974.) £10.95.

THE content of this revised and updated English version of an originally Danish text is summarised well in the description on the dust jacket of the book. "The first section of the book is devoted mainly to Greek physical science... Concepts of nature and of scientific laws in general are discussed in addition to theories within particular sciences. The reader is also introduced to the mathe-

matical and other techniques available for the solution of problems. The second section of the book discusses the transmission, reception and elaboration of these theories in the Latin West, and the science of the early Renaissance is seen as the end-point of the classical tradition. The book concludes with biographical sketches of the philosophers and scientists featured in the text."

Not everyone would agree with the authors' prefatory remark that their omission of a detailed account of early Egyptian and Babylonian science was "inevitable", though it was doubtless expedient for them to limit their already extensive theme. Probably for the same reason they omitted any mention of the rich scientific developments in mediaeval India or China, the early history of pure mathematics, time-reckoning, cartography, and so on. It is, on the other hand, truly inevitable, and a little unfortunate, that Alexander Thom's important researches on megalithic lunar observatories and solstitial sites have been published too recently for inclusion in the text or in the bibliography (updated to 1970).

In the treatment of Greek science emphasis is laid upon the importance of the presocratic belief that causal relationships existed between natural phenomena. Aristotle's adherence to this causal principle (or natural law), coupled with the trend away from mythology towards rational explanation and the Platonic concept of the mathematisation of nature, constituted essential ingredients of subsequent scientific thought. Menaechmos's discovery of the conic sections (in about 350 BC) may have arisen from the study of the daily shadows cast by a gnomon upon the ground. That was a hidden empiricism which is also detectable in the Pythagorean relationships between number and harmony, the Method of Archimedes, and the pneumatical experiments of Strato Philo and Hero at Alexandria during the Hellenistic period of Greek cul-

It was, however, mediaeval investigations in optics and statics, founded upon principles drawn from everyday experience, which provided the firmer empirical basis of physical science. The plane astrolabe and mechanical clock were but two of many mediaeval inventions destined to revolutionise astronomical practice; and the rejection of the Aristotelian belief in a causal principle for the explanation of motion was the determinative factor in the development of dynamics, which was required to make the physical implications of Copernican astronomy acceptable to Galileo and many of his contemporaries.

The field which is explored is much more complex and extensive than this outline may suggest, and is already familiar to students of early science. The well balanced presentation in one volume is a welcome substitute for the wide range of scattered publications from which the subject matter would otherwise have to be drawn. The extensive bibliographical and biographical references provide a very useful guide to carefully selected primary and secondary sources. The use of vector notation to simplify explanations of the various geometrical devices used by Greek and mediaeval scholars, though a useful heuristic tool, is anachronistic and presupposes that the reader has received instruction in this technique.

I detected only six minor printing errors in the text, but slightly less care seems to have been taken by the authors and publishers in connection with the description of a great many of the accompanying figures.

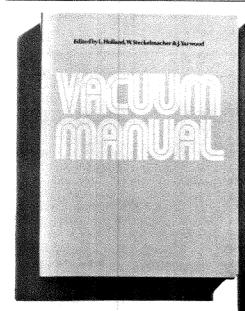

The authors' hope that this book will become widely used as a standard text may be dashed because of its price. The onus is likely to fall upon teachers to obtain library copies and to arrange that these are easily accessible to the members of their classes. My own experience leads me to believe that the clear and scholarly style of this excellent translation, along with the authors' practice of breaking up the text into numerous sub-sections, will appeal greatly to science undergraduates reading the book as part of an introductory survey course in the history of the exact sciences.

Eric G. Forbes

# No matter—never mind

The Brain Revolution. By Marilyn Ferguson. Pp. 380. (David-Poynter: London, 1973.) £4.00.

This book reviews the flotsam and jetsam discovered by those working on the remote shores of the brain sciences. Among other things, it tells us that "human volunteers in biofeedback laboratories are learning consciously to control their brain waves, perspiration, blood pressure, digestive juices and heart rate" (p.17): anyone intending to read it would be well advised to acquire such control first. The authoress tells us that "breakthrough scientists ask silly 'questions" (p.286) and the book parades before us their silly answers. The human psyche is said to be influenced by star patterns, magnetic fields and negative ionisation; precognition and telekinesis are accepted scientific phenomena; the "incredible potency of LSD" (p.123) cures

### THE PHYSICAL **BIOLOGY OF PLANT CELL WALLS**

The Physical Salking of Plant Cell Walk

RDPrestories

R. D. Preston, F.R.S

Chapman & Half: July 1974:518 pages: 140 line illustrations hardback: 412 11600 6: £12.00.

A book which provides a comprehensive and up-to-date account of the present state of knowledge in an area of botanical research which is currently of paramount importance from both academic and commercial viewpoints. The general basis of the book is that the plant cell wall is not an outer excretory product but is an integral part of the cell through which control of growth is achieved. and leading eventually to products of the greatest importance to man.

#### **VACUUM MANUAL**

L. Holland, W. Steckelmacher and J. Yarwood

E. & F. N. Spon: July 1974: 436 pages: 54 line illustrations: hardback: 419 10740 1: £10.75. This book is designed as a comprehensive and practical handbook on vacuum science and technology. It provides basic data on most aspects of vacuum technology in concise tabular form and includes three reviews of important recent developments. In addition the manual represents an exhaustive worldwide survey of the vacuum equipment currently available. It lists and classifies the pumps, instrumentation and vacuum systems produced by over 150 of the world's largest vacuum manufacturers, enabling performance characteristics to be compared at a glance.

### Oxford books – new and forthcoming

### **Our Future Inheritance**

Choice or Chance?

#### Alun Jones and Walter F. Bodmer

'This is an important book.... If other scientists would do for nuclear power, environmental pollution, mineral resources, transport, what Jones and Bodmer have done for bio-genetics, there really would be some prospect that social responsibility for science might be shared by the public instead of being left to scientists.' – Lord Ashby in The Times Higher Education Supplement. £4 paper covers £1.25

#### Geomorphology in Environmental Management

An Introduction

#### R.U. Cooke and John C. Doornkamp

In relating geomorphology to management of the environment this textbook offers a new approach to the study of the subject. It concentrates on such practical problems as soil erosion, flooding, landslides, and permafrost, and it includes many case studies. The book should interest students of agriculture, soil science, land management, land planning, geology, and civil engineering, as well as geomorphologists. £8 paper covers £3.50

# Mathematical Theory of Creep and Creep Rupture

Folke K. G. Odqvist

The mechanics of creep of solids is of concern to the designers of high-temperature machines, jet engines, and high-velocity aircraft. In this book a mathematical theory of creep in metals is built up, analogous to the theory of elasticity, comprising theories of beams, membranes, plates, shells, thick-walled tubes, etc. In this new edition full account is taken of developments in the theory since 1966. Second edition illustrated £7.75 Oxford Mathematical Monographs

### Orbital Theories of Molecules and Solids

N. H. March

This book is dedicated to Professor C. A. Coulson who made outstanding contributions to the method of molecular orbitals. It provides a co-ordinated set of authoritative reviews for graduate students both in theoretical chemistry and theoretical physics. The coverage is of band theory of perfect crystals, defect solids, electronic structure of molecules, intermolecular forces, and molecular crystals. £10.75

# Problems in Physical Chemistry

Alexander Wood

This collection of physico-chemical exercises is intended primarily for first- and second-year degree course students in chemistry and applied chemistry, but the inclusion of a few more difficult problems should also make it useful for more advanced students. SI units are used throughout. Skeletal solutions are provided in most cases to highlight the chief features of the problem. Paper covers £1.95

#### Modern Physical Techniques in Materials Technology

Edited by T. Mulvey and R. K. Webster

Practically the whole range of modern physical methods for the analysis of materials is encompassed in this volume. The basic principles of each technique are explained, the essential form of the apparatus needed is described, and sufficient guidance is given for the inquiring reader to evaluate each technique and pursue it further for himself. The book will also be useful to specialists for the overview it affords of the subject as a whole. £8 Harwell Series.

# Solvable Models in Algebraic Statistical Mechanics

D. A. Dubin

The study of exactly solvable models contributes to the understanding of theoretical structures devised to explain physical phenomena. The structure examined in this book is quantum statistical mechanics, as adapted to systems with an infinite number of degrees of freedom, and the author analyses its standard solvable models: the ideal Fermi gas, the ideal Bose gas, the BCS model of superconductivity, and the Ising model. Paper covers £4 Oxford Science Research Papers

# Molecular Reaction Dynamics

R. D. Levine and R. B. Bernstein

This book deals with the molecular-level mechanisms of elementary chemical reactions, emphasizing the important role of binary collisions. The goal is an understanding of chemical and physical rate processes from the fundamental, microscopie point of view. Primary attention is devoted to the physical phenomena and their conceptual interpretation rather than to the details of experimental techniques or theories. £5

psychoses, autism and alcoholism (though according to one study the last cure only occurs "in 50% of cases" since only one out of the two alcoholics treated actually improved, p.124); we can perceive colour with our finger tips when we are not using them for curing cancer by electrical emanations; and we can of course learn effortlessly either by eating "respected scholars" or by having linguaphone records played to us whilst we are asleep.

The language in which the book is written suggests that the authoress may herself have been in ASC (altered state of consciousness) throughout its preparation. Scientists are alternatively "stunned" and "baffled"; discoveries are "astounding", "amazing", "incredible" or "one of the biggest breakthroughs of our times". Her style speaks for itself: "Into the whirlpool of eddying, oscillating, hormones of a human female toss a contraceptive pill. The vigilant brain, taking astonished note of the suddenly escalated progesterone and oestrogen, behaves as if pregnancy has occurred" (p. 219).

Even when she deals with well established phenomena, such as size constancy, the limits of the visible spectrum, or the after-effects of seen movement, Marilyn Ferguson can do no more than invite us to gawp at them: no attempt is made to provide the reader with an understanding or an explanation, and mysteries are conjured up where none exist. In spite of reservations about the way she presents her material, one cannot but admire her industry: there is a 23 page bibliography in which the citations range from Science, through Esquire to the Psychedelic Review.

Although this book cannot be taken seriously, it may be worth asking whether it matters that so much effort is devoted to making specious discoveries and publicising nonsensical theories: after all, the brain may work in ways that are at variance with existing scientific paradigms, and unless someone produces and tests unlikely hypotheses, we would never know. It may even be that some of the unusual findings reported in this book will eventually be validated. Moreover, in the long run science will catch up and false hypotheses and observations will be discarded. In the meantime, it is only the gullible, those in search of a mystery or a sensation, who will give credence to this kind of work: the rest of us either suspend judgement or hear on the grapevine about all the negative results that do not get into the

Sensation mongering research often does, however, have bad effects. First, much of it, particularly in Russia and the United States is funded from public

money which might be better spent elsewhere. Second, scientists may feel a duty to investigate claims made by others, and if the original research is bad this may waste a great deal of time and effort: proving that an effect does not exist is notoriously difficult. It is said that a Nobel prize winner spent three years attempting to replicate some of the experiments on cannibalism in planaria without success. Third, current trends to mysticism are given a scientific prop. Not all mysticism is bad but mysticism based on bad science is likely to be bad mysticism. Fourth, and most important, when the 'discoveries' are in the brain sciences, they often fall into the hands of medical practitioners, the most gullible of professional people; and when applied to human patients such discoveries can cause a great deal of suffering. Leeches and calomel have now

Ernst Mach (sporting a splendid moustache) lying on his back and sketching the outside world as it presents itself to his left eye. From Logic, Labels, and Flesh. By Stefan Themerrson. Pp. 202. (Gaberbocchus: London, July 1974.) £3.60 boards; £2.40 paper.

been abandoned, prefrontal leucotomies and insulin-induced coma are on the decline, but psychoanalytic therapy still thrives in the face of the evidence, and there is an increasing fashion for amygdaloid lesions and for maintaining children with that mysterious syndrome "minimal brain damage" on large doses of amphetamine.

Perhaps the research councils should establish teams of sceptical but tolerant scientists prepared to move to trouble spots and investigate, in collaboration with the original discoverers, any seemingly outrageous claims that might be of importance either for science or human life. No doubt, on most occasions, they would merely put out the flames expeditiously, but occasionally a really important discovery might be rescued from scepticism, and

at least we might have firm answers to such questions as whether acupuncture works by some process other than blind faith, or whether learning can be transferred from one animal to another by injecting a homogenised brain extract. It does seem extraordinary that no definitive answer to this last question can be given 15 years after it was first raised.

N. S. Sutherland

#### Neuroteleology

Logic of the Living Brain. By Gerd Sommerhoff. Pp. ix+413. (Wiley: London and New York, 1974.) £5.75.

In 1950 Sommerhoff published a book entitled Analytical Biology: it deserves to be more widely read than it has been since it is one of the best philosophical analyses of teleological terms. He argued that a system may be said to be goal directed when its outputs correlate with variations in the states of the environment in such a way that for a wide range of environmental states the same end condition is achieved. He named this concept 'directive correlation' and tried to formalise the idea. His new book attempts a grandiose synthesis of brain and behaviour, and had it too been published 24 years ago, it would doubtless have met with the measure of critical acclaim that in that distant age greeted other pot-pourris of the kind, such as Hebbs' Organisation of Behaviour. Like such books, it would also have been forgotten by now.

In the first section of his new book, Sommerhoff argues that biologists and psychologists have been unable to grapple with the real complexity of the brain because they have not had a set of objective scientific concepts appropriate for the description of a system that is goal directed and that forms and uses models of the outside world. He alleges that brain scientists, by avoiding all teleological language, either oversimplify the problem of how the brain controls behaviour or else they use teleological language in a confused and non-objective way and thereproduce muddled theories. fore Unfortunately, no instances are given of the muddles that arise and one can only speculate about who all these confused theorists are.

Sommerhoff's solution to this problem is two-fold: first, to make use of his earlier idea of directive correlation; and second, to construct nerve nets with classificatory functions that can change through learning. In the second half of the book, he looks at various behavioural phenomena and tries to show how they can be explained in terms of these two ideas.

The book has several serious faults:

#### Scientific Research in British Universities and Colleges 1973\_4

Published annually by the Department of Education and Science, these volumes aim to provide brief details of active research in British universities and other institutions during the current academic year. Each volume is divided into broad subject fields and the university/ polytechnic/college entries are arranged alphabetically within them. Information on science and history and philosophy of science appear in all three volumes. Volume III, Social Sciences, additionally gives details of research within some Government departments and other nonacademic institutions. There are name and extensive subject indexes in all three

'An indispensable guide to every branch of science . . ,' EVENING STANDARD.

Vol I (Physical Sciences) £7.70(£8.06)
Vol II (Biological Sciences) £6.50(£6.80)
Vol III (Social Sciences) £6.50(£6.80)

#### Report of the Technical Committee on Backsiphonage in Water Installations

Prepared by the Department of the Environment, this important publication investigates the problems of backsiphonage in water installations and advises on the precautions that are necessary to prevent it. Backsiphonage is interpreted to include all types of backflow whereby water intended for drinking and domestic use may become contaminated.

#### M HMSO BOOKS

First, it is often wildly inaccurate. For example, it is stated that "The assumption that reinforcement can directly strengthen responses which precede it by a time interval of more than a few seconds is contrary to the evidence" (p. 167). Second, Sommerhoff seems for the most part to be unaware of recent psychological work and theorising. This vitiates his account of language and animal behaviour, whilst enabling him to set up as Aunt Sallies Hull and Tolman who, except from the view point of the historian, no longer merit serious discussion. Third, the book contains a number of errors in logic. For example, Sommerhoff argues that pattern recognition is based on eye movements: he claims (p. 272) that it is easier to translate the extent and direction of an eye movement into a directional vector than to translate a retinal distance: he forgets that, since saccades are ballistic movements, the brain must compute visual angle and direction from the retinal image before initiating the eye movement.

Finally, and most importantly, despite the block diagrams and mathematical flourishes, the concepts Sommerhoff himself introduces do not seem to provide any new explanations of known phenomena and are less powerful than the concepts and explanatory models in current use by workers in the field. Thus, his classificatory and learning networks are not powerful enough to cope with what is known about the visual perception of objects, and his introduction of the notion of 'expectations' in this context remains vague. On the other hand, he is clearly aware that perception does involve the problem of inference and the construction and accessing of representational models, but he does not refer the reader to any of the extensive work that has been undertaken on such problems over the last decade.

The basic neural networks suggested by Sommerhoff are simple, but they do have a certain elegance. For example, he shows how, with the use of recurrent or forward inhibition, it is possible to construct networks that have the properties of flip-flops. The difficulties begin when he tries to explain complex behaviour or information processing by making more elaborate models in which his simple networks are put together into complex structures. At this point, the models become far from clear, and it is impossible to know whether they would behave in the way that is claimed or not: the only way to find out would be to simulate the models on a computer but Sommerhoff has not attempted to do this. Indeed, he dismisses the analogy between brains and computers in a few pages early in the book. He points out several differences between the hardware of existing

computers and that of the brain, but this is not really what is at issue, since computers are so constructed that they can be programmed to model any logical system within the limits imposed by their storage capacity and processing time. Having in this way foresworn computer simulation, he leaves himself without any good tool for constructing and testing models of the processes that underlie behaviour.

Throughout the second part of the book, Sommerhoff makes a valiant attempt to tie up function with brain anatomy. He assigns more or less plausible roles to some of the known connections in the brain, but in terms of the complexity of the tissue and of the behaviour which is controlled the assigned functions tend to be rather simple. The relationship between the evidence and the theorising is, as he himself admits, frequently tenuous.

The book is well written, and should bring a glow of nostalgia to those who pine for the slap-happy fifties when we could raise two cheers for anyone bold enough to tell us how behaviour could be taken care of by some neural nets and a few connecting tracts.

N. S. Sutherland

#### Scientific rambles

Science and Values: Patterns of Tradition and Change. Edited by A. Thackeray and E. Mendelsohn. Pp. viii+251. (Humanities Press: New York, 1974.) \$11.00.

In spite of its rather grand title, this collection of essays is a useful example of some pioneering work in the history of science. A more accurate title would have been "Science (or better, Scientists) in Social Context"; or even, considering parts of the text "What Some People Can Get Up To With Science". The editors disclaim any intention to air comprehensive or synthetic views: what they present are papers exploring strongly "contextual" approaches to the history of science from Rome to Tokyo, and from Manchester to Madagascar. This miscellany is the product of the Van Leer Jerusalem Foundation Conference in 1970.

With such rapid enlargement of the horizons of historical research it becomes difficult to find a theme common to even a few of the essays. The volume starts with a brisk general survey of the changes in English science since the eighteenth century leisured gentleman gave way to the nineteenth century worried middle class. There is a blow by blow description of the "Ayrton incident" of 1872, when the absolute supremacy of the Hooker dynasty at Kew Gardens was challenged by the eccentric Ayrton.

then Commissioner of Works. Thanks to Ayrton's removal because of an unrelated embarrassment, the scientific establishment escaped the humiliation of being rendered publicly accountable for their stewardship of public funds.

The most sensitive piece of 'externalist' historical writing comes from the American Charles Rosenberg, who describes the strategies of agricultural researchers returning from Germany in the 1850s. Here, we find cultural context, administrative constraints, and personal self-estimation, woven together very beautifully.

But the reader is not permitted to tarry on these familiar scenes; the anthropology of science beckons. Early nineteenth century Madagascar, its rulers anxious for 'magicians' to provide the tools of power, attracted a mixture of industrial, political and clerical entrepreneurs. This early "Technical Assistance Programme" failed to Europeanise the culture, though in a half century it did cause its decay.

Further east yet, to Japan and China; a sociological consideration of western style academic politicking in Tokyo, and the study of propaganda by a group of 'scientising' Chinese, who for a time after the First World War saw this as the truly modern alternative to Confucianism. With a sigh of relief we are brought back to the Europe of the 1920s, and a little tour of the great centres of theoretical physics. As a conclusion there is a highly theoretical essay on "The Authority of Science in Politics", which argues the implications of the presence of two discrete audiences, scientific and lay, with different criteria and concerns.

Does this amount to anything more than a record of a pioneering effort in a field which is no longer quite so pioneering? It certainly provides a warning that 'the social context' of science is vast and various and that scholars will need a strong hold on their material if it is not to baffle researchers and students.

#### Politics and changes in the weather

Weather Modification in the Public Interest. By R. G. Fleagle, J. A. Crutchfield, R. Johnson and M. F. Abdo. Pp. ix + 88. (University of Washington: Seattle and London, July 1974.) £2.85; \$5.95.

Any good work of science fiction depends on one or two critical, and possibly fantastic, assumptions from which all the rest follows logically. In a similar way this study by Fleagle and his co-authors depends on the assumption that weather modification will become posible on a substantial scale, with reasonably predictable outcomes. Given this, the book discusses logically the political, legal, administrative and management structure which will be needed to control weather modification.

Some weather modification has already been demonstrated as practical—the clearing of cold fogs, for example—but that has raised few administrative problems. The seeding of orographic clouds to increase the snow and rain over mountains has also been practised for many years, apparently with some success, but that has not raised serious legal problems. If, however, a government agency could modify or divert hurricanes, or if it initiated cloud seeding on a grand scale then no doubt greater problems would arise.

There is a danger that the reader of this book who lacks a strong meteorological background will be led to believe that the potential of weather modification is much greater than has so far been proved, which may lead him, or her, to accept as necesary the somewhat elaborate organisation recommended in the book.

In the few legal actions brought in the United States under the quite extensive legal framework already established, none of the plaintiffs has been able to establish a cause-effect relationship between the actions of the weather modifier and the alleged results. This points to the premature nature of any elaborate legal or administrative framework.

On the other hand, the well-briefed meteorologist will find much of interest in the history of weather modification in the United States and in the views of the authors on future developments.

Whether or not one accepts the view that weather modification will be used on a wide scale in the future, an activity which currently involves the expenditure of around \$20 million of public funds in the United States certainly deserves public discussion. Furthermore, it is well to recall also that almost \$3 million is spent annually on cloud seeding by American companies operating abroad. The international aspects cannot be ignored: the effects may be greater on international relations than on climate.

The Freud/Jung Letters. Edited by William McGuire. Pp. xlii+650. (Hogarth Press, and Routledge and Kegan Paul: London, 1974.) £7.95.

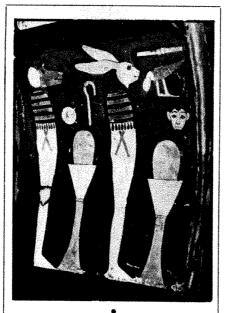

THE publication of this volume marks an important contribution to the history of the psychoanalytical movement, comparable to the issuing, in 1954, of Freud's letters to Wilhelm Fliess. Following his communications with Fliess. this exchange of material with his later protagonist, Jung, formed another chapter in the development of Freud's ideas. It is, perhaps, as the chronicle of a fruitful but doomed relationship that the volume has its greatest appeal, and as such, it forms a useful pendant to the official versions which have been given by Ernest Jones and by Jung himself.

When reading the letters, one is struck by the extent to which differences were managed for such a long time. For those familiar with the account of the break as given in *Memories, Dreams*, and *Reflections*, the tolerance demonstrated by Freud in the last years is unexpected. Yet the need felt by both men explains the concessions, the reconciliations, even the tensions that led to the final parting. A letter sent by Freud in 1907 sums up the situation beautifully:

. now of all times I wish I were with you, taking pleasure in no longer being alone and, if you are in need of encouragement, telling you about my years of honourable but painful solitude . about the indifference and incomprehension of my closest friends, about the terrifying moments when I myself thought I had gone . . about my slowly growing conviction, which fastened itself to the interpretation of dreams as to a rock in a stormy sea, and about the serene certainty which finally took possession of me and bade me wait until a voice from the unknown multitude should answer mine. That voice was yours" (p. 82).

Amid the intellectual torpor of the Burghölzi Hospital, Jung responded in kind. The meeting of two such gifted ninds inevitably acquired complicaions, for as Jung looked to Freud in erms of a father figure, so too the older nan regarded his younger colleague as i son and heir. Freud wanted Jung to explore schizophrenia in the way that ie himself had studied obsessional neuosis (p. 168). But even though Jung and begun to do that before the corressondence began, his reservations about in exclusively sexual origin for mental Ilnesses were evident from the first pp. 4-5, 7, 79, and 138-139). Later, as ung developed his own theories about he mind, disagreements became more narked. After Jung's lectures in America in 1912, an open break was invitable and it came within a year.

Publications and personalities fill

Hare-headed divinity of ancient Egypt on the coffin of Bakenmut, 21st dynasty. From *The Leaping Hare*. By G. E. Evans and D. Thomson. Pp. 262+24 photographs. (Faber: London, October 1974.) Paper, £1.50.

many of the letters, but the editor William McGuire aids the reader with footnotes which are concise as well as informative. It is a well produced book with lucid translations by Ralph Manheim and R. F. C. Hull, useful appendices, and an index. Finally, thanks should be given to the estates of both men for allowing the publication earlier than had been expected.

B. A. Boucher

#### Fifty year's minutiae

Half a Century of Medical Research. Vol. 1: Origins and Policy of the Medical Research Council (UK). A. Landsborough Thomson. Pp. xiv+308. (HMSO: London, June 1974.) £4,60.

WORTHY, rather than exciting, is the appropriate adjective for this book. It is the first of two volumes which will deal with fifty years of medical research in England. This first volume covers the history of the Medical Research Council and articulates the earlier principles of policy insofar as the future administration of the council and the future developments in scientific programmes are concerned. What comes out of this book—and, one can confidently expect, from the volume to follow-is almost every kind of fact and statistic that anyone interested in such matters could possibly hope for. Do you wish to know the details of the relevant Ministry of Health Act of 1919? Then this book will tell you just how this act was passed and how a very necessary legislative pro-

vision was inserted to cover the question of "The organization of enquiry and research on health activities". Do you wish to know the minutiae of the administrative organisation of the Medical Research Council: which subcommittee was formed to do this or that; that the title Second Secretary, first used in 1949-57 and revived in 1965, is now established for an officer able to act as the Secretary's secondin-command and deputy; that in 1914 rooms for temporary offices were taken at St. Stephen's House, Westminster, at a rent of £25.00 per annum, and that the council moved to Park Crescent in September 1961, into a building with a frontage of 255 feet with a depth of just over 42 feet? The book abounds in items like these.

As a living history I have to confess I find it lamentable, though as a compendium I find it invaluable. Nothing of the vibrating personalities emerges at all, nothing of people's real feelings, nor any real analysis of the infinite complexity of issues. So much is written up as a scientific Jennifer's Diary. We are told, for example, that on the occasion of the council's Jubilee Dinner, celebrated in November 1963, the Duke of Edinburgh was prevented from attending but that Lord Shawcross presided. In the absence of the Prince, The Right Honorable Quintin Hogg proposed the toast and a reply was made by Sir Henry Dale, but nothing of what was actually said on this occasion is recorded. Perhaps no-one really said anything-perhaps no-one knows; but I can hardly believe that. To add that: "The presence of Lady Fletcher and Lady Mellanby at the high table was particularly appropriate", may add something to our edification but nothing to our education.

This book is terribly safe; it says nothing controversial. There is very little that one can object to except that it is dull. Only a few notes of human vitality and spark emerge from the thumping melodic line. So, like drops of water in a desert, we read that the secretary of the council on February 2, 1939 wrote: "The discussion then wandered from the point and as we were both tired of cursing each other. we satisfied our minds by cursing everybody else". It is good to know that someone has a sense of humour. This is a book for the library but, unless you suffer from insomnia, it is not for the bedside.

I think it is a great pity that the sponsors have not been better served. The Medical Research Council, in achievements and policy, is an institution that we can contemplate with warmth and pride, and its history deserves a more vigorous and dynamic treatment.

June Goodfield

#### The Senses of Animals

WYKEHAM SCIENCE SERIES NO. 26 E. T. Burtt/A. Pringle

This account starts from our own sensory experience and seeks to learn about the senses of other animals by analysing their behaviour, the electrical responses of sensory nerves and the structure of sense organs. The senses of other animals often differ from our own in range and sensitivity, and some animals possess senses not present in the human, such as the electrical sense of many fish.

#### Vertebrate Hard Tissues

WYKEHAM SCIENCE SERIES NO. 30

L. B. Halstead/R. Hill

Vertebrate hard tissues, from bones and teeth to horn and eggshells, are traced through their different levels of organisation from molecular and cellular to the tissues and organ systems. These tissues are examined from the standpoint of biochemists, molecular biologists, histologists, anatomists, physiologists, palaeontologists, bioengineers and pathologists. The aim is to provide students with a comprehensive view of the subject covering the entire spectrum of approaches at a reasonably elementary level. Emphasis throughout is on comparative and evolutionary aspects.

#### The Astronomical Telescope

WYKEHAM SCIENCE SERIES NO. 31

B. V. Barlow/A. S. Everest

A short review of ancient astronomy is followed by a descriptive account of telescope development from the earliest instruments to projects planned for completion by 1980. Brief revision of fundamental optical science precedes treatment of all the important aspects of telescope design and usage. Time-keeping and spherical astronomy, essential to star finding, are explained, as are items of photometric and spectographic equipment. Practical aspects of observatory site selection are discussed and the advantages of extra-terrestrial telescopes explained. The book concludes with a look at new developments such as faint star finding.

# Astronomy for astrophysicists ...

Gamma-Ray Astrophysics. Edited by Floyd W. Stecker and Jacob I. Trombka. (A symposium held at NASA Goddard Space Flight Center, April, May 1973, sponsored by NASA and the American Physical Society.) Pp. xvi+412. (Scientific and Technical Information Office, NASA, Washington, DC, 1973.) \$2.90.

ASTRONOMY has been one of the most prolific of modern sciences, but the gestation period of one of its offspring  $-\gamma$ -ray astronomy—has been painfully long. The conception was in 1958 but it was not until 1972, after many false alarms, that birth finally occurred. This book is the report of a symposium on  $\gamma$ -ray astronomy which was held at the Goddard Space Flight Center in April 1973, and, therefore, marks a significant stage in the subject.

The papers read at the symposium illustrate very clearly the current situation in y-ray astronomy and the great differences between that subject and the neighbouring X-ray astronomy. X-ray astronomy began in 1962 with the unexpected discovery of an X-ray source outside the Solar System. This discovery was made with a detector of modest size on a short rocket flight; experimentalists immediately realised that, with the use of larger detectors and the much longer exposure times provided by satellites, a rich field was waiting to be exploited. By contrast, few results were forthcoming in γ-ray astronomy until the experimental techniques had been stretched almost to their limit. This aspect of the subject is illustrated by the experimental contributions to the symposium, many of which contain a great deal of discussion of the statistical significance of observations, and of the reality, or otherwise, of differences between experimental results.

Conference reports inevitably reflect the vices and virtues of conferences and this one is no exception. One of the worst aspects of conferences is the superficial manner in which each topic has to be treated because of the limitations of time; nearly all of the contributions to this symposium, both experimental and observational, have been treated much more fully in various journals. Many scientists believe that the real value of conferences are the discussions which take place outside the formal sessions. Obviously, this activity is not recorded in a report but something is retained in the reporting of the question time at the end of each session. Here, one finds a genuine element of criticism and discussion by Schwartz and Gursky of the mally in journals. A very valuable paper at the symposium was the discussion by Swartz and Gursky of the experimental problems encountered in measurements of the spectrum of the diffuse flux of cosmic γ rays. This feature was discovered as early as 1964 but the problems of eliminating the effects of atmospheric background radiation and the effects of cosmic ray interactions in the detector still have not been solved. A critical discussion of the experiments in this field was long overdue.

One of the breakthroughs in 1972 was the discovery by Chupp and his coworkers of y-ray spectral lines from a flare on the Sun. A paper by Ramaty, interpreting these results, illustrates the potential value of measurements of this type to our understanding of the role of high energy particles in flares. There is a contrast between this theoretical contribution and others which discuss subjects such as the decay of radioactive nuclei in supernova remnants, the interactions of cosmic rays in intergalactic space, and the possible effects of large scale regions of antimatter in the Universe. These discussions lack the discipline imposed by reliable experimental results and the more hardened experimentalists will look upon them with a degree of cyni-

The second breakthrough—the discovery of  $\gamma$ -ray bursts from outside the Solar System—was not published until after this symposium, but it was thought to be sufficiently important for two papers on the subject to be in-

cluded in the report.

The final session of the symposium was a discussion of future trends in γ-ray astronomy. This discussion leaves one with the impression that all γ-ray astronomers are aware of the difficulties facing the subject but that some, at least, are optimistic. The low price of this report, its clear format and its quick publication combine to make it an attractive summary of the current state of this branch of astronomy.

R. R. Hillier

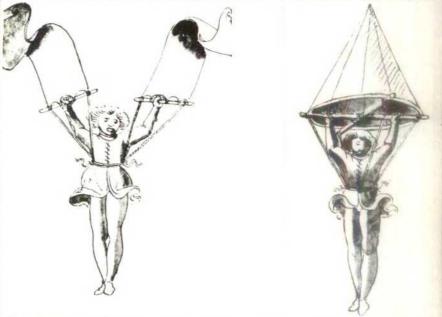

# ... and for arts students

Concepts of Contemporary Astronomy. By Paul W. Hodge. Pp. viii+547. (McGraw-Hill: New York, 1974.) \$9.95; £5.45.

Fundamental Astronomy, By Franklyn W. Cole. Pp. xiiiix+476. (Wiley: New York, 1974.) £5.30.

With deafening regularity new books on astronomy hit the librarians' tables, all aimed at that enormous amorphous bunch of students known as "nonscience majors" who annually flock to American universities to take degrees in liberal arts and letters. One gets the impression that no American publisher worth his salt can produce the yearly book list without at least one Introduction to Astronomy, Fundamental Astronomy, Modern Astronomy, Principles of Astronomy, New Horizons in Astronomy, Stars and Galaxies we Ought to Know and Love, Concepts of the Universe, The Universe and Beyond!, Mysteries of Space, and so on.

The teaching of science to arts students is obviously a good thing.

Parachutes: optimism and progress. Anonymous sketches from the late fifteenth century. The first recorded drop (probably an entirely appropiate word) was made in 1783. From Scientific Technology and Social Change. (Readings from Scientific American.) With introductions by Gene I. Rochlin. Pp. 403. (W. H. Freeman: SanFrancisco, 1974.) \$6.95.

Science impinges constantly on everyday life and ought to be understood at least in part. Astronomy is the most accessible science to the arts student: after all isn't every thinking person a cosmologist? Even the child ponders earth, space and time, their beginning and end. And astronomy is central among the sciences, gathering knowledge and expertise from a myriad of scientific specialities. Both the significance and insignificance of man in relationship to time and the universe are clearly illustrated.

But how should the arts student be approached? Most of the books seem to regard him as a rather stupid, inumerate, failed scientist. Surely this student has a different outlook on life from scientists, an outlook bred on comparison and criticism and aesthetic judgement, a preoccupation with why as opposed to the narrower scientific how. Science should be able to learn as much from arts students as they do from scientists, and these books should help and encourage arts students to play their part in quenching the thirst for knowledge.

Both the books under review are good in their own way. Both are clearly written in a concise and everquestioning style, continually leading the reader to grasp the enormities of the problems being tackled by astronomers and the many pitfalls on the way to understanding. Both books are lavishly illustrated with photographs of instruments, planets, stars and galaxies and, especially in Hodge's book, with thoughtfully designed simple line figures.

Each book considers basic astronomical concepts, the Solar System, stars and galaxies; however, Cole has slightly more emphasis on the Solar System, Hodge emphasising stellar evolution. Both books stress observation: Cole has an excellent appendix on observational astronomy for beginners; Hodge concludes each chapter with a fascinating hist of suggestions for simple experiments and observations. Some of these require simple laboratory equipment or a small telescope or high powered binoculars but many require only impoverished equipment that can be put together at home.

Choosing between the two books I would pick Hodge's Concepts of Contemporary Astronomy: the best book on astronomy at this level that I have read for many years. Hodge has thought very carefully about the needs of the students he is writing for and gives hem not only a knowledge of the nature of the universe but also an appreciation of the methods of science. But I still have a hankering to read an istronomy text written by an arts graduate. I wonder what they really make of it. David W. Hughes

#### Sources of streams

Fluvial Processes in Instrumented Watersheds: Studies of Small Watersheds in the British Isles. By K. J. Gregory and D. E. Walling. Pp. iii + 194. (Institute of British Geographers Special Publication No 6.) (Institute of British Geographers: London, February 1974.) £4.25; \$10.60.

THIS latest volume by the British Geomorphological Research Group reports the results of major process investiga- rather than competitive with, that tions in small catchments in Britain. The work involves contributions in four major areas: the origins and controls of run-off and of sediment and solutes. The objectives of the studies range from basic assessments of the volume and frequency of inputs and outputs to the basin, to formal testing of deductive models. For the most part, however, the work is empirical and much of it applied or capable of direct application. It should attract the attention of practising civil engineers as well as researchers.

Two dilemmas are brought out

clearly in the volume and referred to by the editors. The first is that within the basin there are important spatial and temporal variations in processes whose effects are integrated in sediment, solute and water yield at the output. Unfortunately, the output is where the monitoring of the basin is likely to be easiest and least expensive. In choosing small basins where one process tends to dominate, this dilemma has been partly avoided. Moreover, the work then becomes complementary to. carried out by other research organisations. The second dilemma is that with the rapid development of the subject, model building alternately precedes and succeeds data collection for testing. The solution seems to be the closer integration of the two areas of research.

This is an important addition to research in geomorphology and perhaps to hydrology. Despite an over-imaginative use of the linear regression model, it indicates a very healthy state in a key area of concern in environmental research and management.

John B. Thornes

#### Earth science by numbers

Geomathematics: Mathematical Background and Geo-Science Applications. By F. P. Agterberg. Pp. xvi+596. (Developments in Geomathematics, vol. 1.) (Elsevier: Amsterdam, London and New York, 1974.) Dfl135; \$54.00

This book surveys the mathematical methods and statistical techniques used in the study of data obtained from various types of physical and chemical sampling of rock and rock strata at the Earth's surface. It is not, as its title might imply, a comprehensive survey of the mathematical methods used in general geophysics. Rock samples, and geological data generally, are characterised by very great variability and so it is not surprising that this book concentrates on probability and statistics.

The book is unique in that these statistical methods are illustrated by many examples drawn from geology. In a way it is strange that it was biology rather than geology that provided the stage for the development of modern statistical methods. Lyell had in an appendix to his Principles of Geology divided the Tertiary into four periods on the basis of the proportion of species found in these rocks living today. But on the whole the field geologist, unlike the agriculturalist, did not find it easy to record in a simple numerical form the various pieces of information he collected and perhaps remained unconvinced of the value of doing so. It was of course the long series of carefully

marshalled numerical data at Rothamstead that gave the late Sir Ronald Fisher the impetus he needed to lay the basis of modern statistics.

It is, however, interesting to note that the impetus from the development of a statistical theory of variation in two and three dimensions resulted from the accumulation of data on the distribution of cross bedding directions and palaeomagnetic data respectively. All this is now changed and this book will be of great value to the geologist.

S. K. Runcorn

Statistical Methods for the Earth Scientist. By Roger Till. Pp. 154. (Macmillan: London and Basingstoke, 1974.) £5.00, boards; £2.50, paper.

THERE are few really readable books on statistics in general and even fewer aimed specifically at the earth scientist, but Dr Till is to be congratulated in joining a select and much needed band. The book is intended as the basis for a 40 hour course in statistics for undergraduate or postgraduate students with no previous background in statistics, and only simple algebra. It is a small volume-9.5 by 6 inches-with a content ranging from the basic philosophy of statistics up to analyses of variance, regression and some non-parametric tests. These are covered in a comprehensible way with examples drawn from mainly sedimentological and geochemical sources, although care has obviously been taken to include at least

one example from each of the main branches of earth science.

The book should form an excellent basis for a very elementary course (even less than the prescribed 40 hours) as it not only covers the basic concepts but also gives ample warnings of the standard pitfalls into which so many senior earth scientists have fallen—and are still falling. To quote one example, not used in the book, radioactive isotopic dates invariably include their precision, that is, the repeatability, yet most earth scientists still take these figures as measures of accuracy, at least until they conflict with their own ideas.

Other credits are good references and the avoidance of that frustrating phrase "it can be shown that"; instead Dr Till refers the reader elsewhere, usually to Yule and Kendall, for a more rigorous explanation but even that is rare. The publishers also deserve credit as the book is well produced and designed, although certain figures (for instance, 5.5, 5.6 and 5.7) are really too big and, if reduced, would not only have saved paper but would also have improved the appearance of the book.

The index covers only statistical subjects, and it might sometimes be necessary to find out where porosity or grain size is considered. But the only real fault is the scope: the range of analyses covered is much too short for the cost of the book and it would also have been a better buy if more statistical tables had been included.

I hope that Dr Till will be encouraged to expand this introductory text to include, for example, much fuller consideration of directional properties so that this book, if still sold at the same price, could become an essential text at the start of any earth scientist's career. But at the moment it does not go far enough.

D. H. Tarling

#### Model methods

Analytical Methods in Planetary Boundary-Layer Modelling. By R. A. Brown. Pp. xii+148+5 plates. (Adam Hillger: London, June 1974.) £8.00.

THE scope of this book is narrower than one might guess from the title. It deals primarily with a restricted topic in the theory of the Earth's atmospheric boundary layer, namely the mean velocity distribution in stationary, horizontally homogeneous, and neutrally stratified conditions. Particular emphasis is placed on the matching of an upper Ekman layer with a surface layer unaffected by the Earth's rotation. Concluding chapters consider the effects of non-neutral stratification and non-stationarity, but the treatment is very superficial. There are also two chapters on the instability of Ekman layers and the relationship between that and meteorological observations; this

is the best part of the book but its connection with the rest is not made clear.

For whom is this book intended? The author offers no indication, and the level of difficulty is so variable that one cannot guess. Who is the mysterious reader who can comprehend the equations of fluid motion with no derivation and little explanation, but who requires an elementary explanation of the procedures of dimensional analysis; who is already familiar with the properties of geostrophic flow, but not with the basic derivation of centripetal and Coriolis accelerations; who knows what is meant by "the eddy flux of potential heat", but who can usefully read a most superficial summary of the properties of thermal convection?

Meteorology students might benefit from a text leading up to current views of the atmospheric boundary layer through explanation of the now classical topics of Ekman layer theory and micrometeorology; synthesis of those topics is not so commonly discussed. Brown's book is, however, neither comprehensive enough nor lucid enough to serve that purpose. The derivation of the well known logarithmic profile, for instance, would be quite incomprehensible to anyone not already familiar with it.

Errors in the equations and algebraic expressions are sufficiently numerous to provide further reason for not recommending the book to readers unfamiliar with the subject. Most of the errors are probably misprints (although there are too many of them for this to be acceptable as an excuse). But there are incorrect signs on pages 49 and 79 which invalidate the subsequent algebra; and equation (3.19) is, I suspect, a misprinted version of an incorrect equation.

Research workers in fluid dynamics and meteorology may occasionally find the book a useful source on those topics for which the information is not gathered together elsewhere. But this purpose could have been fulfilled more effectively and economically by a review article on, for example, 'Ekman' layers in meteorology'.

D. J. Tritton

#### There's still no place like Holmes

Earth. (A series of books in Geology.) By F. Press and R. Siever. Pp. xi+945. (W. H. Freeman: San Francisco, July 1974.) £6.60.

THE authors of this book have impeccable qualifications for writing it, both as active research scientists and as university teachers. They say that it is intended for students who have had no previous college science courses; and they express the hope that it is as up to date as a current meeting of the Geological Society of America (it was finished in December 1973) and that at the same time, it is as understandable as today's newspaper. These intentions are commendable and the task they have set themselves is difficult; it is interesting to see how they tackle it.

The level throughout the book, which is splendidly produced and illustrated, is such that after reading it the diligent student should experience no difficulty with specialist papers in Scientific American. Plate tectonics figures large and early. The first 150 pages-"The earth as an historically evolved body and how we study it"-serve to introduce the vocabulary. They start with an account of the origin of the Solar System, which I found interesting because I knew nothing about it, and finish with a long chapter on rocks and minerals. Part II covers the traditional field of physical geology. Part III introduces the fields of petrology and geophysics and this section is written at a marginally higher level than the others; for example, a chapter on the formation of igneous rocks touches on Bowen's reaction series and on the problem of the origin of granite batholiths. I wonder, however, whether the 27 pages on plutonism and metamorphism really equip the reader to dip into F. J. Turner's book *Metamorphic Petrology* which is quoted in the bibliography.

How, then, does the book live up to its authors' intentions? Trying to cope with a readership which is assumed to be entirely without any scientific education has made the book unmanageably long. Was it necessary to devote three pages (115-118) to defining words like topography and contour? The need to start the chapter on weathering with the very beginning of inorganic chemistry makes it impossible to discuss the peculiarities of the weathering of rocks at all. The desire to encompass pass present and future in one large sweep reminds me of the phrenetic enthusiasm of geophysicists running an open day in the laboratory. For example, in chapter 3 ("How we find out about the earth") we have a photograph of a Benioff strain seismometer, a section on experimental petrology and a 'box' about Cavendish's 1798 determination of G, together with 13 other topics all introduced in the course of 22 pages. The book is certainly not dull, but I wonder whether the American college student has the stamina to read its 945 pages. I do know that the English girl studying for 'A' levels on whom I tried it, had not. In this field Holmes remains ancient but unbowed

D. H. Matthews

#### **Broad spectral lines**

Spectral Line Broadening by Plasmas. By Hans R. Griem. Pp. xiv+408. (Pure and Applied Physics: A Series of Monographs and Textbooks, vol 39.) (Academic: New York and London, May 1974.) \$31.50; £15.10.

An earlier book by this author, entitled 'Plasma Spectroscopy', has served for many years as a reference source for spectroscopic research in experimental plasma physics and astronomy. The popularity of that text, written in 1964, can be gauged by its high demand in departmental libraries, and the frequency with which it is encountered in spectroscopic laboratories. The new monograph treats a more specialised topic: spectral line-broadening mechanisms for neutral and ionised atoms in quiescent plasmas, and in nonequilibrium plasmas which exhibit suprathermal electric field fluctuations. It thus expands and updates chapter 4 of the earlier book, and similar theoretical reviews of the same vintage by Baranger, Van Regemorter, Traving and others

Professor Griem introduces his subject with an admirably concise survey of the foundations of Stark broadening theory, and the derivation of the quasi-

'A pioneer work which is likely to remain essential for . . . those who nowadays have an interest in the quality of the air we breathe.' Nature 55 figs.

£6.25

static and impact approximations. Detailed examples of practical calculations using these two extreme, but complementary, approximations are then given; these are followed by a discussion of various intermediate approximations (phase integral, relaxation, dynamical and one-electron) for situations in which the frequency shift relative to the unperturbed line frequency is neither much less nor much greater than the characteristic frequency for single, binary, collisions with charged perturbers. Several other characteristic frequencies may enter the general problem. Thus, magnetic field and plasma correlation effects (Debye shielding, plasma polarisation shift and satellites caused by plasma wave fields) are selected and discussed in the final sections of a chapter which comprises some 40% of the total text. (In his preface the author wisely, though modestly, advises the experimentalist that a 'minimum theory' approach has been adopted.)

The next fifty or so pages constitute a highly selective, and therefore most interesting, critique of experiments which have provided important checks on overall accuracy, and validity limits to the various theoretical approximations. Most definitive experiments have been made on laboratory plasmas with electron densities of 1013-1019 cm $^{-3}$ , and temperatures of 2  $\times$  10 $^3$  - $2 \times 10^7$  K. This density regime is much more restricted than that of current practical and computational interest, which ranges from approximately 10<sup>3</sup> cm<sup>-3</sup> (H II region) to 10<sup>26</sup> cm<sup>-3</sup> (stellar interiors and laser fusion). Similarly, the available temperature range is still one or two decades less than that of thermonuclear interest. The experimenter should note how frequently density gradients have caused real complications in the interpretation of line shapes, even when some other, independent, density measure is also available. Relatively few line-broadening analyses seem to have been reported for heavy-ion hydrogenic lines and for lines in third and higher spectra, although plasma polarisation effects can be of particular significance to the latter spectra, because reliable corrections are needed to deduce the corresponding energy levels of isolated atom. At sufficiently high densities, neutral helium emits lines with forbidden components, involving transitions in which the angular quantum number does not change by unity.

More generally, the electric fields associated with suprathermal plasma waves will modify the line shape, and can excite satellites symmetrically disposed about the position of forbidden components. The third chapter, describing key experiments, therefore con-

cludes with a discussion of recent attempts to probe the intensity and orientation of turbulent electric fields, by measuring the intensity of sidebands on H<sub>B</sub> profiles in two orthogonal directions, and by analysing the polarisation of the emitted spectrum. Satellites on He I lines associated with electron and with ion plasma oscillations have also been identified; in some of these measurements wave energies three to four orders of magnitude above thermal levels were inferred. A particularly pretty example of the sophistication of present theory and experiment is illustrated in Fig. 28, in which Cooper and Hess have resolved fine structure caused by the Zeeman effect on a forbidden line, and on plasma satellites, by comparing  $\pi$  and  $\sigma$  polarisations

For the many of us who are users rather than specialists in the subject. the fourth and final chapter provides a very convenient summary and conclusion to the text. It outlines various practial applications, including determinations of plasma density and temperature, and the investigation of strongly excited collective modes in nonequilibrium plasmas; stellar emission, radio frequency lines from galactic regions, and the importance of the wing shapes of resonance lines to opacity and radiative transport calculations are briefly discussed. It also serves to introduce numerical data tabulated in some hundred pages of appendices. (Such information should be augmented in the future by infor mation collated at a data centre recently established at the National Bureau of Standards.)

One valuable service provided by a book of this sort is the correction of errors which have crept into the literature; such errors are discussed, for ex ample, at equations (207), (394), (395) and on pages 150, 176, 204 and 215 (references 145, 59, 258 and 38, respectively.) Presumably to avoid further errors, and to reduce costs, many of the tables are reproduced as computer printout; in the review copy some of these were difficult to decipher (for example, Table 3), but this constitutes only a minor criticism concerning the production of a book which is attractive to read, well organised and realistically priced. Professor Griem and his research school have made very significant contributions to this subject, and the book should be well received at a time when a topical interest in laser-fusion plasmas should give the subject a fresh lease of life. In this connection, it may be noted that the effects of extremely high densities, in which the plasma electrons obey Fermi-Dirac statistics, are not discussed explicitly.

Dr. H. MOENKE

#### Atomspektroskopische Spurenanalyse

(Atomic Spectroscopy in Trace Analysis)

(Moderne Spurenanalytik, Band 1)

146 Seiten mit 33 Abbildungen und 22 Tabellen. 16,5 cm x 23,0 cm

Leinen 39.- M

Bestell-Nr. 669 760 8

The first volume deals with the various analytical methods available to atomic spectroscopy, and with their application in trace analysis. In the book's concise but nevertheless comprehensive survey of these methods-flame emission, spectrography, atomic absorption and fluorescence as well as laser-microspectrum analysis, measuring equipment and applications—the reader obtains a general view of the potential of atomic spectroscopy as applied to trace analysis. Additionally, the sections dealing with measuring equipment and their various spheres of application offer invaluable information on the choice of methods and apparatus necessary in various jobs.

#### Dynamics of Degeneration and Growth in Neurons

Wenner-Gren Center International Symposium Series – Volume 22

K Fuxe Karolinska Institute, Stockholm, Sweden L Olson & Y Zotterman, Wenner-Gren Center, Stockholm, Sweden

616pp

US\$60.00

ISBN 0 08 17917 7 h

This book contains the proceedings of an international symposium held in Stockholm in May 1973, concerning recent advances in some basic concepts of neurobiology related to growth of neurons. Aspects of these phenomena are discussed both in general and in most of the lectures specifically with regard to the monoamine neurons. Methods include biochemistry, histology, electron microscopy, histochemistry, pharmacology, neurophysiology, behavior tests, etc.

#### Contents

Opening Address. Degeneration Processes in Peripheral and Central Neurons. Axoplasmic Transport as a Mechanism for Axonal Support and Growth. Growth. Receptor Changes in Relation to Degeneration and Development of Neurons and Drug Treatment.

The Chemistry and Biochemistry of the Sulfhydryl Group in Amino Acids, Peptides and Proteins

M Friedman Wool & Mohair Laboratory, United States Department of Agriculture

485pp US\$22.50 ISBN 0 08 16845 0 h

"A comprehensive, well-referenced account of the chemical properties of the sulphydryl group with special reference to biochemical systems. This book covers a wide range of topics, starting with a detailed consideration of the ionisation properties of sulphydryl groups, followed by a comprehensive presentation of the chemical reactions which they undergo, ending with chapters on the reactivity of protein sulphydryl groups, Biochemical Pharmacology and Medicinal Chemistry. This is an invaluable book for advanced undergraduates, postgraduates or research workers in chemistry and the biological sciences."

# An Introduction to Spectroscopic Methods for the Identification of Organic Compounds

In two volumes

Edited by F Scheinmann University of Salford

The prime object of this two-volume work is to show the novice how spectral data can be translated into the structural formulae of organic compounds, and to provide reference data and revised correlation tables for the initiated.

Volume 1 201pp US\$8.50 ISBN 0 08 006661 5 h US\$5.00 ISBN 0 08 006662 3 s

#### Contents

An introduction to high resolution nuclear magnetic resonance spectroscopy; Applications of nuclear magnetic resonance spectroscopy in organic chemistry; Correlation tables for nuclear magnetic resonance spectra; Nuclear magnetic resonance spectroscopy seminar problems and answers; The theoretical basis of infrared spectroscopy; Applications of infrared spectroscopy to organic chemistry; Infrared spectroscopic problems and answers; Correlation tables for infrared spectra; Wavelength wave number conversion table.

Volume 2 354pp US\$12.00 ISBN 0 08 016719 5 h US\$ 7.00 ISBN 0 08 016720 9 s

#### Contents

An introduction to mass spectrometry; Mass spectral seminar problems and answers; Ultra-violet spectroscopy applied to organic chemistry; Answers to seminar problems in ultra-violet spectroscopy; Theoretical aspects of ultraviolet spectroscopy; An introduction to electron spin resonance spectroscopy; E.S.R. seminar problems and answers; Some recent advances in nuclear magnetic resonance spectroscopy; Elucidating structures of organic compounds using a combination of spectral methods; Seminar problems and answers for identification of organic compounds using a combination of spectral methods; The documentation of spectral data.

#### LEADING SCIENTISTS AGREE!

"...a highly commendable collection of material which will be valuable to chemists of all kinds" commented Professor Sir Harold W. Thompson, F.R.S. Oxford. "...will undoubtedly remain the standard first source of information in this area for many years to come" wrote Professor N.N. Greenwood, F.R.I.C., Leeds, Professor C.C. Addison, F.R.S., concurs, "...quite remarkable, in that they can justifiably claim to be comprehensive, yet at the same time remain interesting and readable; they are probably unique in this respect."

#### INDEPENDENT OPINION

"Highly Recommended" by CHOICE, which wrote, "Since the length and cost are not prohibitive, this set of books should be well within the budget of most libraries. Not only will professional chemists find these books useful but students and other readers will find them a valuable reference source. These should be in every graduate and undergraduate library, as well as industrial libraries. Many Professional Chemists must even consider them for their personal libraries."

NEW TECHNICAL BOOKS asserts "the work deserves a place in all general science collections."

# **ADAM HILGER PRIZE**

#### Announcement of a Competition

Adam Hilger Ltd invite entries to a competition for the best previously unpublished book or monograph in English offered to them for publication on any subject that qualifies for inclusion within the broad embrace of earth and planetary sciences, in which knowledge is nowadays being gained at so lively a rate that there is urgent need to consolidate in volume form the gains already made. Environmental studies, scientific in character and related to the quality of life, will be considered no less relevant than, say, geology, oceanography, geophysics, geochemistry, and planetary science, so that the competition offers plenty of scope to authors. The prizewinning entry, and any other entries deemed of sufficient merit, will be published in volume form by Adam Hilger Ltd. The rules are as follows:

- The Adam Hilger Prize will amount to £500. In addition, the Adam Hilger Prizewinner will receive a royalty on all eventual sales of his book.
- Adam Hilger Ltd reserve the right to award further prizes for entries considered to be of sufficient merit. They also reserve the right to award no prize if no entry is adjudged of sufficient merit.
- Subject to signature of a standard form of publisher's agreement, a copy of which may be obtained at any time from Adam Hilger Ltd, the author of every work accepted for publication, including the Adam Hilger Prizewinner, will be paid a royalty on all eventual sales of his work.
- The Adam Hilger Prize will be awarded in 1977 for the book adjudged best among the entries received in typescript on or before 31 December 1976. Entrants therefore have over two years in which to prepare their entries.
- The name of the Adam Hilger Prizewinner, and of any other entrant who may win a prize in the competition, will be announced in the Press. Any prizewinner will also be notified direct.

- Adam Hilger Ltd will have the exclusive right to publish, and the right to refuse to publish, any of the entries, but each entrant will retain the copyright of his work and will be able to offer the work for publication elsewhere if it is deemed unsuitable for publication by Adam Hilger Ltd.
- Tentries must be original and must not infringe any existing copyright. They must be of high quality and must make substantial and useful contributions to the literature of their subjects. They must be suitable for publication in volume form, and so may be expected in general to need lengths of 50,000 or more words and to be appropriately illustrated.
- The principal adjudicator will be Professor A. J. Meadows, Department of Astronomy, University of Leicester, but entrants should not communicate with him direct as far as their entries are concerned. In selecting the Adam Hilger Prizewinner, the publisher's decision will be final.
- Intention to enter for the competition should be made known to Adam Hilger Ltd as soon as possible.
- 10 The competition for the Adam Hilger Prize is not open to any employees of the Rank Organisation or its subsidiary companies.

Recently published books by previous winners of Adam Hilger Prizes are Atmospheric Waves by Tom Beer, University of Ghana, and The Chemistry of Clay-Organic Reactions by B. K. G. Theng, University of Bonn. Available for inspection in libraries, they will show entrants the standard at which to aim.

# Mathematical theory of elasticity

Introduction to Rational Elasticity. (Monographs and Textbooks on Mechanics of Solids and Fluids.) By C. C. Wang and C. Truesdell, Pp. xii+556. (Noordhoff: Leyden, 1973). Dfl. 130. FOLLOWING the precedent created by his joint work with Noll in presenting the non-linear field theories of mechanics Truesdell has now collaborated with C. C. Wang to bring together recent work in the mathematical theory of elasticity. As Truesdell points out in his introduction, there has been a dearth, until recently, of rigorous theoretical work on the existence and uniqueness of solutions to problems of elastic materials. With completely new techniques in pure mathematics becoming more generally understood, however, the stage is set for advances in many branches of applied mathematics. If this book inspires pure mathematicians to embark upon the application of rigorous mathematics to problems in applied mathematics and, in particular, elasticity then the authors' aims will have been vindicated and the colossal price of the book perhaps justified.

For those readers not familiar with the recent advances in pure mathematics, the book opens with a chapter which present the concept of a finite dimensional vector space, the concept of a manifold, and a section on Lie groups. This chapter is, as the authors admit, an outline of ideas, and many readers will need to study more deeply the topics covered before feeling confident to proceed further. Chapter II considers the more general subject of continuum mechanics, of which elasticity is one aspect. It is suggested that a reader whose interest lies solely in elasticity may ignore this chapter—that would be very unwise because in chapter II is the development of the ideas of constitutive relationships upon which modern elasticity theory is based. These relationships are further developed in the context of elasticity in the third chapter, which also contains a number of the inequalities satisfied by an elastic body, together with an introduction to the uniqueness and stability of solutions of elastic prob-

Homogeneous and inhomogeneous bodies are studied in the following two chapters, and chapter VI contains a discussion of wave propagation. In that chapter the less mathematical reader will recognise many familiar results and it could be argued that a good introduction to rational elasticity might be obtained by a superficial reading of chapters IV-VI before embarking upon a detailed study of these and

the earlier sections of the book.

The final chapter presents a unified account of the present state of knowledge of the existence, uniqueness and stability of the boundary-value problems of elasticity. This is the climax of the book for the mathematician and should leave him in no doubt that there are still many problems worthy of his skilled attention.

A. H. Craven

#### Crystal behaviour

Dislocations and Plastic Deformation. By I. Kovacs and L. Zsoldos. (International Series of Monographs in Natural Philosophy, Vol. 60.) Pp. xii+343. (Pergamon: Oxford and New York, February 1974.) £3.50.

This book aims to provide an introduction to dislocation theory, followed by an account of the mechanical properties of crystals, including the yield stress, work hardening, creep, and effects of heat treatment. It covers much the same ground as Cottrell's famous book Dislocations and Plastic Flow in Crystals, but attempts to update and enlarge upon that work, now 20 years old. It is a difficult task, for the boundary between dislocation theory and plasticity is as much of a no-man's land as ever, and Kovacs and Zsoldos can only list the conflicting theories of work hardening without leaving the reader much wiser; a student will find this chapter heavy and demoralising.

It is unfortunate that the treatment is so exclusively devoted to tensile stressstrain curves of pure face-centred cubic metal single crystals: a wider discussion of the experimental observations would be rewarding. Another general criticism of the book is that it omits many recent developments: there is no mention of Foreman and Makin's computer experiments on yielding, which have greatly clarified the subject; no mention of weak-beam measurements of stacking-fault energy and no mention of diffusion creep. Finally, the book contains a number of errors, perhaps the most glaring being the expression for the energy of a straight dislocation on page 48, which leads to erroneous expressions for the line tension on page 64, and this in turn, together with the omission of weak-beam results, leads to a rather unbalanced assessment of the current value of stacking-fault energies.

In spite of these defects, the book is more comprehensive and up to date than any now available, and provided the graduate student has read Cottrell's book referred to earlier, this book can be used as an introductory text in a field where few are available.

L. M. Brown

# ENGINEERING FROM LONGMAN

The Experimental Method Edited by R K Penny

This book describes methods for planning, conducting, analysing and reporting experimental work; chapters are presented in the order in which these topics usually arise. Special attention is given to the number of observations needed.

Cased £3.95 net Paper £1.95 net

Ten Cases in Engineering Design H O Fuchs and R Steidel Inr In this book the student is confronted with real life incidents drawn from actual practice and is given an opportunity to review decisions made by responsible engineers, and the outcome of these decisions, as well as professional procedure. An essential feature of the ten case studies presented is the faithful representation of the problem by those involved.

£3.95 net

Vibration of Linear Mechanical System Systems

H McCallion

A detailed explanation of the basic concepts of the subject. It will provide the reader with a sound understanding of some of the modern sophisticated computer based techniques for vibration analysis.

Cased £5.95 net Paper £3.95 net

Foundations of Engineering Mechanics G R Higginson

This book, which has been written for engineering undergraduates, aims to create interest rather than simply to convey large amounts of information common to most textbooks on the subject.

Cased £4.50 net Paper £1.95 net

Stress Analysis of Polymers J G Williams

"Essentially a basic text in stress analysis developed from first principles, the book's emphasis on polymer materials makes it a welcome addition to the engineer's basic armoury at this time."

#### Methods for cool operators

Low Temperature Laboratory Techniques: The Use of Liquid Helium in the Laboratory. Second edition. By A. C. Rose-Innes. Pp. 255. (English Universitiies: London, 1973.) £3.95.

This is a new edition, brought up to date (although no references are later than 1971) and expanded with sections on developments since 1964. The main sections are concerned with the temperature range above 1 K, with coverage of the handling of helium, cryostats, and the design of apparatus, and the measurement and control of temperature. Towards the end are chapters on the use of 3He (including dilution refrigeration, but not Pomeranchuk refrigeration) and on temperature measurement below 1 K.

The advice given is at an unusually detailed practical level, often to such an extent that every dimension and technique seems to carry a personal guarantee. The numerous figures reinforce this feeling by their directness and simplicity. I can see the value of this approach, particularly for the beginner who often has to take responsibility for the lowlier aspects of research without the author's experience. Inevitably, with such a laboratory-workbook format there are places where the reader may wish to add, remove or alter, but on the whole it is a useful collection of highly practical tips. The data tables are also helpful.

There are a number of unnecessary variations of notation (for example He<sup>3</sup> on p. 193; helium<sup>3</sup> on p. 194; ml on p. 22; cm3 on p. 23); misprints (I enjoyed "owl temperature" on p. 99 and "aneroid" on p. 114 among others) and unnumbered equations. Generally, though, appearance and visual clarity are good.

D. S. Betts

#### Nuclear structure

Theoretical Nuclear Physics. Vol. 1: Nuclear Structure. By Amos de Shalit and Herman Feshbach. Pp. xxviii+ 979. (Wiley: New York and London, June 1974.) £14.60.

THE appearance of this volume is a notable event for nuclear physicists and yet another reminder of the loss to the scientific community caused by the untimely death of Amos de Shalit. It is the first of two volumes covering essentially the whole of nuclear physics; this one is devoted to nuclear structure and a forthcoming volume will cover nuclear reactions

The authors aimed to cover all the important ideas as clearly as possible, and in a way that will inspire as well as instruct, and they have succeeded brilliantly. A brief summary of the contents will indicate the scope of this encyclopaedic work.

The first chapter is an introductory review of nuclear physics, dealing with nuclear sizes and masses, forces and energies, and also with nuclear systematics, regularities in nuclear spectra, electromagnetic properties of nuclei, high energy scattering and reactions and associated topics. Subsequent chapters are devoted to nuclear models, starting with the simplest that likens the nucleus to a Fermi gas. There are sections on the Weisäcker mass formula, one and two-particle densities, coulomb energies and the nucleonnucleon force and nuclear stability. Next comes a chapter on nuclear matter, basic to the understanding of nuclear properties. The independentparticle and independent-pair approximations are described, together with the Bethe-Goldstone equation and its solution.

Two chapters are devoted to the independent particle and shell models. It is shown how the single-particle shell model with either an harmonic oscillator potential or a more realistic rounded and finite potential is able, provided a spin-orbit term is included, to account for many basic features of nuclear structure, in particular the magic numbers and the spins, parities and magnetic moments of nuclear states. The model works best for nuclei near closed shells, but it is also shown how it may be extended to nuclei with several particles outside closed shells, and its success is illustrated by examples. The Hartree-Fock self-consistent field theory is developed and applied to closed and open-shell nuclei. The method of classifying nuclear states with the help of the concept of isospin is described and illustrated by examples, using various coupling schemes. There are also sections on particle-hole configurations, fractional parentage coefficients and configuration mixing in many-particle systems.

Away from closed shells it becomes increasingly difficult to use the shell model to describe nuclear states because of the very large numbers of possible configurations, and for such nuclei the collective models are often more appropriate. In such models many nucleons are assumed to move together, either as a rotation or as a vibration of the whole nucleus. With an appropriate collective Hamiltonian it is possible to calculate many of the properties of such nuclei.

The theory of multinucleon systems is considered next, with a detailed account of the Hartree-Fock theory, the random phase approximation and the free quasi-particle system, all using the second quantisation formalism. There are sections on the pairing interaction, the linked-cluster expansion, the Brueckner-Hartree-Fock theory, the local density approximation, the pairing-plus-quadrupole interaction and the microscopic theory of valence forces.

The last two chapters are devoted to electromagnetic transitions and weak interaction phenomena. After a description of the nuclear electromagnetic current and the quantised electromagnetic field the selection and sum rules governing electromagnetic transitions are obtained and illustrated by examples. The section on weak interaction begins with the theory of  $\beta$ decay and goes on to consider different types of transitions, orbital electron capture, antineutrino absorption, electron-neutrino angular correlation, the helicity of the neutrino, muon decay, vector currents, forbidden beta decay and absorption of muons by nuclei.

This brief summary of the main topics can do little to indicate the wealth of detail and comprehensiveness of the coverage of the book. It is difficult to think of any important aspect of nuclear structure physics that has not been covered, and the vast range of topics is welded into a coherent whole.

The treatment is generally at the graduate student level, and requires only a general familiarity with nuclear physics such as may be obtained in an undergraduate course. It will also serve as a valuable reference book for undergraduates and a handbook for professional nuclear physicists.

P. E. Hodgson

# Denial of quantum physics

The Interpretation of Quantum Mechanics. By Michael Audi. Pp. xiv+200. (University of Chicago: Chicago and London, 1973.) £5.75.

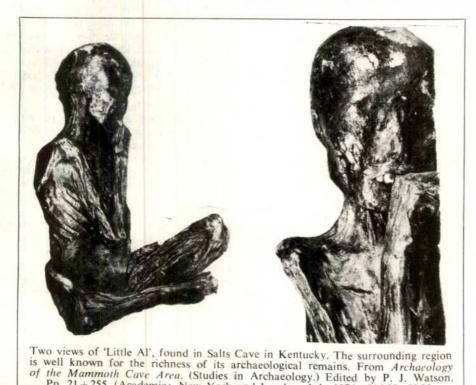

THE main purpose of this book is to show that the classical conception of a particle, particularly the attribution of simultaneous position and momentum to a particle, can be carried over to quantum mechanics. The core of the argumentation runs as follows: classical mechanics can be separated into two parts. First, a material body can be represented as a coffection of particles, each particle having at all times an exact position and an exact momentum and thus travelling in a continuous path in space. Second, the path of a particle is determined by laws of motion. In quantum mechanics, however, there exist no laws of motion for atomic particles, and the indeterminacy of observations is due to the unpredictability of the paths of material atomic particles.

This means, of course, that it is erroneous to ascribe any wave property to a material atomic particle. Conversely, the particle property of photons is denied. A photon is considered to be oscillations in the electromagnetic field, and all the experimental evidence of the corpuscular character of electromagnetic radiation is explained as "discrete interaction properties" of the electromagnetic field with matter. Obviously this amounts to a

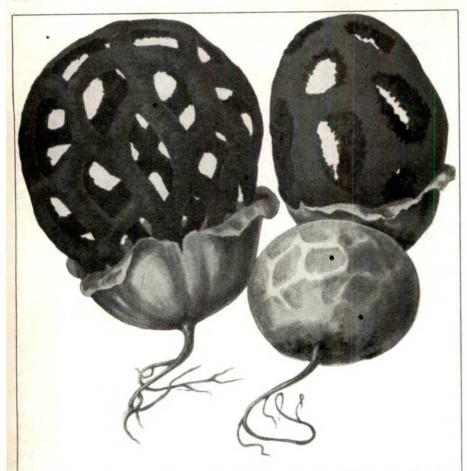

total rejection of the complementari

By means of his thesis about th unpredictability of the (postulate paths of material atomic particles, th author is to some extent capable protecting his classical conception an atomic particle from the exper mental facts in quantum physics. Br on page 106 it is rightly stated the satisfactory interpretation quantum mechanics must provide a explanation of crystal diffraction phenomena. Now the classical partic concept will come to its crucial tes the reader thinks. But instead of intre ducing in some statistical way th postulated particle trajectories, the it cident beam of particles is represente in the usual quantum mechanical wa by a plane wave function, which then perturbed by a periodic potentia representing the crystal. Though it indeed an interference phenomeno which the author sketches in the calculations, he does not like to sa so. Multiple slit experiments are treate along the same line, and the argumer ends up with the rather cryptic state ment that each particle in the bear passes through one particular slit, bu nevertheless, more than one slit is ac ing on the particle.

The parts of the mathematica scheme of quantum theory involve in the argument are far too sketchil presented and several equations at blurred by misprints. Also, the author seems to minimise the significance ( points which oppose his basic position and in some cases he simply leaves or such points. For instance, the Coper hagen interpretation of quantaum mech anics is said to be inconsistent because it claims that quantum physics contain classical physics as a limiting case an yet it does not consider atomic particle as classical particles. One should expec then, that the author would examin very carefully the correspondence be tween the two fields of experience. O pages 34-35 he claims to have skatche a derivation of the classical Hamilton Jacobi equation from Schrödinger equation in the limit where the quantur of action can be considered to b vanishingly small. It really cannot b called a derivation because it involve equations which are mathematically ob jectionable, and, furthermore, the mos important result in this connection namely that the wave packet repre senting the atomic object moves accord ing to the laws of classical mechanics is left out. Yet this result shows that the complementary behaviour of atomi objects displayed through interference phenomena and particle phenomena fully compatible with the classical par ticle concept, applying, of course, onl to observational situations where th quantum of action can be neglected.

Pp. 21+255. (Academic: New York and London, July 1974.) \$16.00; £8.00.

Clathrus cancellatus. One of hundreds of illustrations in Mushrooms and other Fungi. By Augusto Rinaldi and Vassili Tyndalo. (Translation by Italia and Alberto Mancinelli.) Pp. 333. (Hamlyn: London and New York, November 1974.) £6.95.

The author's thesis about atomic particles means, in fact, the rejection of quantum physics itself. If the reciprocal limitations in the applicability of the space-time concepts and the momentum-energy concepts expressed by Heisenberg's indeterminacy relations are not fundamental, but can eventually be overcome by improvements in observational techniques and theoretical methods, then there exists no universal quantum of action and no quantum physics.

T. Bergstein

#### **Molecular chemistry**

nternal Rotation in Molecules. Edited by W. J. Orville-Thomas, Pp. xvii+606. (Wiley-Interscience: New York, 1974.) £13.50.

The last thirty years have seen considerable activity in the study of internal rotation and related ring puckering motions in molecules. Or-ille-Thomas' extensive volume is timely, containing a chapter on all of the main techniques and the results which can thus be obtained. It is, unfortunately, an edited volume with eparate authors for each chapter, a scheme which leaves a few gaps and inroduces some duplication and variation of style. It is a pity that the editor

did not impose a *fiat* on the question of units for barrier heights: the choice of kcalorie mol<sup>-1</sup> dominates over the more favoured kJ mol<sup>-1</sup> by about 2: 1. It is perhaps inevitable, but many of the chapters take space to introduce fundamentals, so that the volume includes unnecessary introductory accounts of nuclear magnetic resonance (n.m.r.), gas microwaves, electron diffraction and acoustics.

Gas microwaves provide the single most valuable technique for gaining information about the gas phase and the topic is covered by N. L. Owen in a fairly short but effective chapter. Electron diffraction, described by A. H. Clark, is valuable chiefly for indentifying the dominant conformation, and in some cases for evaluating the trans-gauche ratios. Acoustic work, described by S. M. Walker, covers the kinetics of the transformation, although the size of dispersion also indicates energy and volume differences between the interconverting systems. There is also a helpful chapter on theoretical work, covered by A. Veillard, from which it is clear that elaborate ab initio calculations can evaluate the barriers effectively although it is not easy to extract simple qualitative information about the origin of the

# Gradient liquid chromatography

Gradient Liquid Chromatography. By C. Liteanu and S. Gogan. (Elli Horwood Series in Analytical Chemistry). Pp. xii+358. (Ellis Horwood; Chichester, Distributed by John Wiley. Halsted Press: New York, July 1974.) £10.50.

This work reviews the principles, practice and application of liquid chromatography using various types of gradients in eluent and stationary phase composition, and in temperature. The review is comprehensive up to 1969 or 1970 but the authors have unfortunately failed to react fully to the recent development of high performance liquid column chromatography and the practical parts of the book are somewhat dated although still useful as a basis for development.

In reviewing the theory the authors are too uncritical and by quoting numerous mathematical results, often without adequate explanation, they have failed to explain the principles of the subject as clearly as they could have. This is unfortunate in an otherwise useful work for it limits its value to practising analytical chemists who badly need a clear and simple exposition of this important topic.

John H. Knox

barrier from such complex wave functions. Simpler functions are ineffective in predicting the barrier heights.

One of the difficulties in this field is the major influence of solvents, and in liquid phases the effective barriers and potential minima may be quite different, a point strongly emphasised by R. J. Abraham and E. Breitschneider. The regular tools for liquid-state studies include n.m.r. and dielectric methods.

Other chapters complete the picture which, overall, amounts to a great deal of work by many research workers. There is sufficient knowledge to allow most unknown barriers to be inferred by analogy and interpolation, at least in the organic field. References to completely inorganic molecules are very sparse and there did not seem to be any reference to the intriguing motion which makes all the fluorine atoms indistinguishable in PF<sub>5</sub> at higher temperatures. A formulae index would have added greatly to the usefulness of the book.

Clearly, most specialist science libraries will need this volume, but the overall picture is neither sufficiently clear nor sufficiently intriguing to warrant individual purchase.

D. H. Whiffen

#### **Connective issues**

The structure and Biochemistry of Cartilage. By A. Serafini-Fracassini, and J. W. Smith. Pp. vii+236. (Churchill Livingston: Edinburgh and London, 1974.) £8.00.

This book is a very readable account of the biochemistry of connective tissue components, and of the structure and morphology of cartilage. It provides a good background to the biochemistry of connective tissue and gives an excellent introduction to cartilage morphology with particularly detailed accounts of the epiphysial plate and calcification. In those topics it is a major advance upon existing texts.

The first half of the book gives a detailed account of the structure of elastin, collagen and the glycosamino-glycans. The subject is treated thoroughly and would do justice to a more general text on connective tissue biochemistry. Much of the information is contained in numerous tables which compare chemical compositions and amino acid analyses, and list physicochemical properties. This concise way of presenting data is backed by a text that is informative and to the point, which greatly enhances the value of the book to the general reader.

The molecular biology of connective tissue macromolecules is probably the most rapidly developing field of research relating to cartilage, and the inevitable delay between the finish of literature searches and publication has produced some points at which these sections are now out of date. For example, there is little emphasis on the different genetic species of collagen present in different tissues. The distinction in composition between cartilage collagen [aI(II)]3 and skin-bone collagen  $[\alpha I(I)]_2$   $\alpha_2$  is described, but their significance as gene products that are tissue specific is not discussed at all. Similarly, new information on the organisation of proteoglycans has shown that they aggregate by binding to hyaluronic acid, forming very high molecular weight complexes within the cartilage matrix. The staining of proteoglycans in cartilage sections for electron microscopy has, therefore, more recently been reassessed taking this into account. The problem that information becomes rapidly out of date is always present to a greater or lesser extent in scientific reviews but in this instance it does not detract from the usefulness of the large amount of additional information presented.

The second half of the book is concerned with the morphology of different types of cartilage. The transition from biochemistry to morphology is bridged by two chapters in which tech-

niques of studying connective tissue components with both the optical microscope and electron microscope are appraised critically, and the general ultrastructure of cartilage is reviewed. The remainder of the book then deals in some depth with the development and structure of the epiphysial plate and with the calcification of cartilage. It finishes with shorter sections on articular cartilage and elastic cartilage. The chapters on the epiphysial plate are particularly worthy of mention as they give a comprehensive account of its development, structure, nutrition, the formation of matrix, and the presence of lysomal enzymes during the subsequent calcification of the tissue. It is difficult to find these topics described in such detail elsewhere.

The book, primarily a text on carti age, can perhaps be criticised for the allocation of excessive space to conne tive tissue biochemistry. Much of the research on the structure of elastin an collagen does not relate directly t cartilage. The book also lacks an attempt at a systematic account of th various types of mammalian cartilag or indeed any discussion of phylogen and for these reasons it cannot be re garded as a comprehensive work. Th general standard of presentation is however, very high. There is an abunc ance of illustrations and a particularl large number of electron micrograph: Each chapter also contains an exter sive bibliography which enhances it value as a reference work.

T. E. Hardinghar

#### Cholinergic transmission – from Russia

Acetylcholine: an Approach to the Molecular Mechanism of Action. By M. J. Michelson and E. V. Zeimal. Translated from the Russian by E. Lesser and Mira Lesser. (International Series of Monographs in Pure and Applied Biology. Division: Modern Trends in Physiological Sciences, vol. 38) Pp. xviii+241. (Pergamon: Oxford and New York, December 1973.) £8.50.

INTEREST in the application of techniques of molecular biology to the study of drug-receptor interactions, in particular at the cholinergic synapse, has grown rapidly in recent years. So the advent of a book claiming to discuss the "molecular mechanism of action of acetycholine" would seem to be of vital and topical concern. But the book fails to generate the interest promised by its title. That may be partly because the authors concentrate much of their attention on the more classical "chemical-pharmacological" approach of determining structure-activity relationships; but it may also reflect the fact that, despite the initial advance afforded by success in the isolation of the cholinergic receptor, further progress in elucidating the molecular events whereby acetylcholine produces its efforts has been disappointing slow.

Nevertheless, the book includes much material of interest to students of cholinergic transmission. The authors describe work carried out by themselves and a variety of colleagues in Russian laboratories over the past 30 years. The reference list shows that most of this work has been published only in Russian, and may therefore be new to English speaking readers.

There is an initial introductory chapter on the electrophysiological and biochemical functioning of the cholinergic synapse, with an interesting account of what seems to be the fire recording of the endplate potential, be Ginetsinsky and Michelson, in 193: There follows a brief but informative discussion on the current knowledge of the chemical structure of choosinoreceptors. Again it is pleasing the read of evidence obtained by Turpae in the early 1960s for the presence of sulphydryl groups in the acetylcholian receptor, which anticipated the experiments of Karlin and his colleagues.

Theories of drug-receptor interac tion are assessed well in the thir chapter but the mathematical trea ments are unnecessarily complicate by the avoidance of conventions symbols. The following three chapter deal essentially with results obtaine from comparing the activities of variety of acetylcholine analogues of both the acetylcholine receptor an acetylcholinesterase, from which th authors attempt to make deduction about the active centres of both mole cules, and about the arrangement of receptors (or subunits of the receptor on the postsynaptic membrane. Unfor tunately, the treatment is length? and repetitive and the derived information is scanty and, at best, equivocal.

The final chapter, on non-synapti cholinoreceptors, draws together dat from a variety of tissues includin feetal and denervated muscle, autone mic ganglia, Renshaw cells and Aplysi giant neurones, and fills in many 0 the gaps left in previous chapters. One again, there is a surprising reference to results obtained by Ginetsinsky an his colleagues on foetal muscle some years before similar observations wen made in laboratories outside Russia. I is to be hoped that publication of this book in English (an excellent transla tion) is a sign that such failures in communication will be less frequent Vasanta Srinivasai in the future.

# Primates: swinging through the trees . . .

Primate Locomotion. Edited by Farish A. Jenkins, jun. Pp. xii + 390. (Academic: New York and London, January 1974.) \$34.00; £16.30.

THE disadvantages of the current tendency to publish compilations of invited articles on specialised subjects are numerous. Though books of this kind have undoubted advantages, common to convenience foods and package holidays, they lack the combination of authoritative overview and synthesis of the single-author volume. One of their most serious weaknesses is that, being invited articles, they escape the wholly desirable quality control that anonymous referees and a critical editorial board can impose. Furthermore, the incautious reader may suffer in a different way when he discovers that only some of the articles are really new. Too often their substance, if not their dressing, has already been published elsewhere

The principal fault of *Primate Loco-motion* is the lack of overview and synthesis. With two or three exceptions the articles are new. They are generally of a high standard, lively, well presented and illustrated. It is apparent that currently at least two major problems are engaging the interest of

# ATLA ABSTRACTS

is published twice yearly and contains current information on "Alternatives To Laboratory Animals". Coverage includes a variety of disciplines in a wide selection of world literature.

workers in the fields of anatomy, primatology and primate palaeontology. One of these—the arboreal ancestry of primates—is long overdue for resurrection; the other—brachiation and human ancestry—is a prime candidate for interment.

Cartmill sets the scene for the former in his discussion of the relative adaptive values of the clawed paw and the prehensile hand for arboreal life. He asks fundamental questions and supplies convincing answers illustrated by a wealth of comparative data from other mammalian groups. Too little attention has been paid in the past, as in this otherwise excellent chapter, to the sensory aspects of hand function. hypothesis, of the primacy of arboreality in the evolution of monkeys and apes is incomplete without consideration of the role of the peripheral sense organs

Chapters from Farish Jenkins on former in his discussion of the relative locomotion of treeshrews, by Szalay and Decker on the evolution of the primate tarsus and by Walker on the locomotion of present day prosimians, pursue this theme. Jenkins's paper, as becomes an editor's contribution, is particularly sound and lacks any element of witch-hunting which diminishes the stature of some of the other articles. I particularly like Jenkins's final sentence which runs: "The adaptive innovation of ancestral primates was not the invasion of the arboreal habitat, but their successful restriction to it".

The brachiating theme is pursued in the chapters by Lewis, by Roberts on the structure and function of the scapula, and by Tuttle and Basmajian. O. J. Lewis states his views once again on hominoid wrist morphology which lead him to espouse Sir Arthur Keith's theory of the brachiating origin of man in spite of the fact that Keith was basing his views on the gibbon, which Lewis clearly rejects from human ancestry on the grounds of wrist morphology.

Tuttle and Basmajian, reporting on an electromyographic study of forearm muscles of the gorilla, give considerable space to the well aired subject of knuckle-walking in African apes. Their contribution to the brachiating issue is, however, both moderate and sensible

A valuable chapter on the mechanics of locomotion in primates by Badoux, an account of leaping in galagos by Jouffroy and Gasc and an interesting article on the much neglected field of postural activities in Old and New World monkeys by Michael Rose, complete the volume.

Primate Locomotion is an important source book for the graduate reader but the lack of overview and synthesis makes it an unsuitable text for the student.

J. R. Napier

# ... and adapting to other situations

The St Kitts Vervet. By Michael McGuire. (Contributions to Primatology. Vol. 1). Pp. xi+202. (S. Karger: Basel, London and New York, 1974.) Sfr 56; £8.10; \$17.40.

VERVET monkeys were introduced to St Kitts, probably from West Africa, in the latter part of the seventeenth century. Today, they are common both in scrub-covered coastal areas and in the forested ravines running up into the island's central massif, and population densities are similar to those observed in several African field studies. McGuire's monograph reports the results of 6,300 hours of observation by nine observers in nine study areas, and covers population demography, activity patterns, social organisation and communication. Two main findings emerge. First, groups living in the ravines differ in dispersion, activity patterns, and in the frequency of grooming and agonistic interactions from those living in the coastal scrub. Second, 19% of the (54) communicative gestures observed in East African vervets by Struhsaker and 44% of the (48) vocalisations were not recorded in the St Kitts population.

Both comparisons make an important contribution to our knowledge of the adaptability of primate behaviour. Unfortunately, they are spoiled by inadequate quantification. In the first, the reader is asked to take on trust many of the suggested differences and no quantitative evidence is either shown or referred to. Where this is not the case, description of sampling methodology and sample size is scanty and no attempt is made to test the significance of the observed differences. In several cases, the measures used are inappropriate: for example, the "general tension state" of each group was measured by estimating its flight distance from an observer. Comparison with Struhsaker's study is largely confined to qualitative differences and is free from these objections. But the reader is required to accept the author's opinion that the absence of the communication patterns observed Struhsaker is not the product of differences in classification rather than in behaviour.

A second major criticism of the monograph is the amount of turgid and unnecessary discussion which it contains. This suggests that, despite the impressive list of series editors on the front cover, little editorial attention was paid to the manuscript. As a result, material which would fill two medium length papers has expanded into a 200 page book.

# INTERSCIENCE

#### **GENETICS AND THE ANIMAL CELL**

By M. Terzi, Imperial Cancer Research Fund, London.

Cell biology is now very much in vogue and recent techniques have now turned toward the mammalian cell. Large research programmes are concerned with the nature and treatment of cancer; others are concerned with the problems of ageing, human genetics or cellular aspects of development. Students and those involved in research in this "new biology" will want to read this book, for the fact is that more is known about organisms than about their cellular constituents. Dr. Terzi has gathered together a great deal of information about the mammalian cell regarded as a genetic system. He investigates the genetic structure of somatic cell populations and re-examines concepts such as cell senescence, transformation, modulation, differentiation and re-differentiation. He also has new things to say on chromosomal variation and the effects of variations in gene dosage on the behaviour of cell mutants.

#### PHYSICS OF DROP FORMATION IN THE ATMOSPHERE

By Yu. S. Sedunov, Main Administration of the Hydrometeorological Service, Council of Ministers of the U.S.S.R.

Processes of drop assembly formation and condensation growth are considered. Phase conversions during formation and development of clouds are studied. The equation of the condensation growth of an individual drop is analyzed in detail. The Theory of condensation nuclei and the theory of an initial condensation stage are given.

Much attention is paid to the description of kinetic processes for cases when condensation is regular and when meteorological paramenters fluctuate. Fluctuations of these parameters in the atmosphere caused by turbulence are considered. (Translated from the Russian.)

G.K. Hall & Co. announces a major breakthrough in information access:

# The Most Comprehensive Information Source on Scientific Research in Progress Ever Available-Continuously Updated

G.K. Hall & Co., a longtime leader in reference publishing, has arranged with the Smithsonian Science Information Exchange (SSIE) of the Smithsonian Institution in Washington, D.C. to fulfill the research community's need for rapid access to ongoing scientific research: a comprehensive up-to-date information service providing a one-stop reference source on current research in 12 major fields.

Since 1949, SSIE has been maintaining a data base of research in progress, which was available to the research community only through fee-paid computer searches. Now, G.K. Hall will provide access to the over 100,000 records of on-going research received by SSIE each year in a continuing, updated service. This revolutionary new program is called **SATRA:** Science And Technology Research Abstracts. **SATRA** will reproduce the detailed reports of current scientific research, with summaries and indexes, on Computer Output Microfiche. The comprehensive information will go directly from the SSIE computer data base to microfiche to the **SATRA** subscriber on a regular quarterly basis.

#### **SATRA DATA**

Each report about a current scientific research project will contain these facts:

Title of the Project

A DESCRIPTIVE SUMMARY OF THE PROJECT (in 90% of the reports)

Name of Principal Investigator and Co-Investigators

Research Organization

Funding Organization or Supporting Agency

Period covered by the summary of the project

Funding Amount (when reported)

#### SATRA INDEXES FOR SWIFT, MULTIPLE ACCESS

All quarterly updates will also include a set of unique index fiche, keyed to the SATRA number of each project, which provides immediate, multiple access to the information in the 12 subject areas:

SUBJECT INDEX—up to a dozen descriptive terms lead the user to a given project INVESTIGATOR INDEX FUNDING ORGANIZATION

RESEARCH ORGANIZATION INDEX

An initial subscription to a SATRA subject area includes a fully indexed base file of the previous year's reports plus three updates with the set of unique indexes. A hard copy of the Subject Index (to the base file and updates) will accompany every set. A ten percent discount will be offered to subscribers to the complete SATRA set.

FIELDS COVERED BY SATRA		YEARLY SUBSCRIPTION

#### Living with cosmic rays

Space Radiation Biology and Related Topics. By Tobias and Todd. Pp. xvi+ 648. (Academic, subsidiary of Harcourt Brace Jovanovich: New York and London, May 1974.) £15.85.

It is perhaps surprising to see the publication of this volume now when support for space research is declining. It is, however, soon apparent that the manuscripts for all but the final chapter were conceived and written in the late 1960s when the achievements of the US space programme were at a climax and the future for space research looked a good deal brighter than it does today.

The 12 chapters of the book have been written by 16 authors, including the editors, who are expert in a wide range of subjects relating to space radiation biology After a historical survey, two chapters are concerned with the physics of radiations in space. In the first of these the composition and intensity of the radiation fields encountered around the Earth and in the Solar System are described in detail and the radiation doses received by astronauts taking part in the US missions up to Apollo 11, the first lunar landing, are tabulated. In the second, consideration is given to techniques for the simulation of the heavy-ion component of space radiation fields using accelerators.

From chapter 4 onwards the emphasis is on biology, commencing with a review of cellular radiation biology with special reference to heavy-ion radiations. This is followed by a review of the various theories of molecular and biological evolution, again with special reference to the possible role of solar and galactic radiation. One chapter is concerned with the effects of magnetic field on biological systems and another with the results of experiments carried out in satellites where weightlessness can modify the effects of radiation. The

three following chapters deal with mammalian radiobiology in general, the influence on the biological response to radiation of circadian rhythm and the actue and late effects of radiation observed in man.

Chapter 11 is a discussion of the mathematical models used to described recovery from radiation induced injury and the effects of radiation on ageing The final chapter entitled 'Current Topics ni Space Radiation Biology briefly refers to some of the more important developments that have taken place up to 1972.

The volume is very readable, well referenced and adequately indexed and will no doubt be read with interest by both biologists and physicists working in areas related to space radiation biology. It is, then, a great pity that the reader is so often reminded by, for example, the absence of any mention of the chemistry of interstellar clouds in the chapter on evolution, that the book was written several years ago.

K. F. Baverstock

# North American fish fauna

Freshwater Fishes of Canada. By W. B. Scott and E. J. Crossman. Pp. xi+966. (Fisheries Research Board of Canada Bulletin No. 184.) (Information Canada, Ottawa, 1973.) \$9.75.

THE Fisheries Research Board of Canada has a most creditable publishing record on both fish and fisheries. By commissioning a series of excellent publications on the fishes of the major geographical regions of Canada, published in its Bulletin series, it has made the Canadian fish fauna the best documented in the world. In this, the latest of the series, the authors W. B. Scott and E. J. Crossman faced a formidable task in critically surveying the fishes of northern North America, a fauna which in part is poorly studied biologically and is beset with taxonomic problems, while the remainder (mostly the economically valuable species) has been studied in depth. The authors' achievement in bringing together the information in a large literature (over 1,400 references are cited) is alone a major contribution, and their original work welds the whole together to form one of the best books on a major fish fauna to be published this century.

The plan of the book is essentially a systematic account which commences with a key to the families of freshwater fishes in Canada. This relies on simple characters and is amply illustrated; it is clearly a key designed for use by others than systematic ichthyologists—and is all the better for that. Each family is preceded by a key to the species included in the fauna, and though these are necessarily more technical in nature they are still practical keys. The practical nature of the

means of identification is well illustrated by a page of line drawings devoted to the parr of the species of Oncorhynchus, Salmo, and Salvelinus—confusing the young stages of salmons, trouts, and charr.

Each account is illustrated by a drawing of the fish and has text under headings such as description, colour, systematic notes, distribution, biology, relation to man, nomenclature, etymology and common names. Of these headings, biology is frequently the most detailed, especially in the case of economically important species, and provides data on spawning, growth, age at sexual maturity, habitat, food competitors and predators, and parasites.

The more general parts of the book are confined to a brief note on Canada and its fish fauna, which is essentially a listing of the 181 species by geographical area and drainage basin. This seems to be a rather terse treatment of the zoogeography of Canada's fishes strangely so in contrast with the detailed zoogeographic discussions in McPhail and Lindsey's Freshwater Fishes of north-western Canada and Alaska (1970).

Such criticisms as one needs to make of Scott and Crossman's masterly treatment of the Canadian fish fauna are in extra-limital areas. For example, although most books on European fishes report the occurrence of Ictalurus nebulosus, as introduced to Europe, the only specimens critically examined have proved to be I. melas. Surely too, it is time to forget about the death of Henry I of England in 1135 which is said (page 74) to have been caused by eating lampreys (Petromyzon marinus) -although the lampern (Lampetra fluviatilis) was more likely to have been involved Alwyne Wheeler

# Nice balance for ecologists

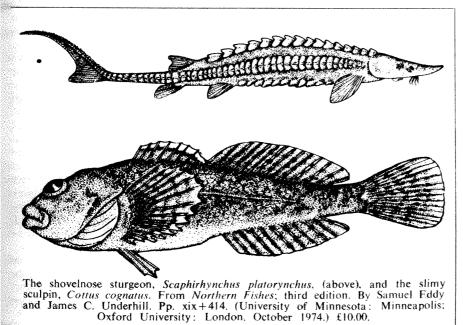

Ecology, with Special Reference to Animals and Man. By Charles Kendeigh. Pp. vi+474. (Prentice-Hall: Englewood Cliffs, New Jersey, 1974.) \$16.95

One of the most frequent criticisms levelled at the examination scripts of modern ecology students is that their knowledge of ecological principles is not accompanied by evidence of experience of living organisms in the field. Ecological field courses were once exercises in field identification; now the recognition of plants and animals has become subservient to studies of ecosystem organisation, trophic structures, population dynamics, pattern analyses, and so on. The pendulum seems to have swung to the other extreme.

Charles Kendeigh's book is unusual in that it attempts to maintain a balance between theoretical principles and detailed accounts of field studies. He achieves this by the insertion of a section which considers certain habitats in detail, including both aquatic and terrestrial examples. By placing this section early in the book, immediately following an introductory section, he demonstrates his conviction that the understanding of ecological principles can only be achieved once the student has become familiar with the diversity of organisms and the complexity of the environment which is to be found in almost any habitat subjected to critical observation. I find this approach both stimulating and refreshing.

There follow three theoretical sections, dealing with ecosystem ecology (nutrient cycling, energy flow, food webs), population ecology and evolutionary ecology. Attempts to simplify language and concept in these sections have occasionally led to misleading expressions, such as the 'energy cycle' and the 'impervious' nature of carbon dioxide and water vapour to long wavelength radiation. Coverage is fairly thorough, however, especially in the section on energy flow, and the relevance of these concepts to the human manipulation and exploitation nature is stressed. The concept of succession is mentioned on several occasions, but a detailed theoretical consideration of this important aspect of ecosystem ecology is lacking.

The coverage of biomes and geographical ecology lacks much of the flow of previous sections. It comprises targely a series of lists of birds and mammals for North American examples of the major biomes. One pleasing feature of these chapters is the inclusion of a few paragraphs dealing with the palaeoecology of the American

biomes, particularly during the Pleisto-

The final chapter, on marine ecology, is rather sketchy and superficial. It gives the impression of being an afterthought.

In my opinion there are three major weaknesses in this book when it is considered as a possible undergraduate text. The first is its lack of information concerning plants. This is particularly noticeable and unfortunate in the chapters on habitat, where it would have completed an otherwise detailed and interesting series of accounts. Although this omission is confessed frankly in the sub-title, it nevertheless reduces the usefulness of the book as an ecological teaching tool. The second weakness from the point of view of British ecologists is its almost exclusive use of North American examples. This must limit severely its value and its sales potential outside the United States and Canada. The third way in which the book could have been improved is by the inclusion of more physiological information about the animals considered. I cannot agree with the author's statement in the Preface that such information is only of value at advanced levels of training.

Despite these reservations I found the style, content and production of this book attractive and interesting.

Peter D. Moore

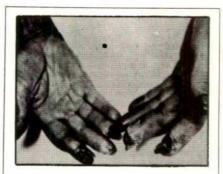

# What is biological control?

Biological Control of Plant Pathogens. By K. F. Baker, and R. J. Cook. Pp. xiv+433. (Freeman: San Francisco, 1974.) \$12.50.

THE authors of this book admit that writing it was a "mind-stretching" exercise; many readers may think that the effort has somewhat distended their subject. The dilemma faced by the authors was how far to extend beyond the difficulty of defining 'biological control' into the wider problems of managing microbial ecology to lessen plant diseases. Early usage of the term fitted well into S. D. Garrett's statement (in Pathogenic root-infecting fungi, Cambridge University Press that biological control is "mediated by one or more organisms (excepting man himself) outside the host-parasite relationship". On page 43 of this book the authors arrive at their much broader and wordier concept: "Biological control is the reduction of inoculum density or diseaseproducing activities of a pathogen or parasite in its active or dormant state by one or more organisms, accomplished naturally or through manipulation of the environment, host or

antagonist, or by mass introduction of one or more antagonists."

This concept is so broad that it embraces all of microbial ecology and much of agriculture, except the use of chemicals aimed solely against pathogens. It is of course commendable that plant pathologists should consider all the factors affecting the biology of plant pathogens but, despite the inevitable demarcation disputes, many would share my preference to restrict the term 'biological control' to the manipulation of 'third organisms' such as hyperparasites, antagonists and competitors. A more comprehensive term would be needed to comprise the important natural environmental artificial factors which

The hands of a workman who had been operating a pneumatic drill for 26 years. The prolonged vibration caused stiffness swelling and, finally, dry gangrene in the fingers. From *The Vibration Syndrome*. Edited by W. Taylor. Pp. xii+226. (Academic Press: London, August 1974.) £6.00; \$15.50.

included as biological in this book; for example, tillage, choice of planting date, and organic and inorganic additives (including fertilisers). In Chapter 9 the authors come perilously close to accepting chemotherapeutants as another factor, thus removing the chief objection to adopting the well established term 'integrated control'.

The first two chapters contain a somewhat unhappy blend of unnecessarily elementary introduction, good sense, and an emotional attitude to unbalanced 'environmentalist' arguments. Both authors have, however, enviable reputations as root pathologists and most of the book comprises a skilled and up to date compilation of knowledge concerning root pathogens. It is comforting to see one chapter devoted to pathogens of aerial parts; but that occupies a mere 20 of the 350 pages of text and so can be no more than an apology to satisfy the completeness that the title suggests. In their preface the authors disclaim comprehensiveness and admit that they have often put a personal interpretation on results which is different from that of the authors they quote. That this is a risky procedure is reinforced

by several authors who claim to have been misrepresented, which breeds doubts about inaccuracies elsewhere.

Inevitably, much of the evidence from the literature is anecdotal and biased, because successes are more often reported than failures (which may be more frequent). With a few notable exceptions it is therefore very difficult to obtain balanced estimates of the value to agriculture of modifications to microbial ecology or control by 'third organisms'. Experience with the decline phenomenon in take-all disease of cereals (Gaumannomyces graminis) suggests that the variability between cropping histories, soils and fields is so great that it will be long before we can confidently predict the effects of antagonists or of developments in biological buffering. These are not, however, reasons for criticising a book that collects together much scattered information, presents it systematically for the first time, and contains more than the usual amount of constructive thinking.

Plainly, the authors did not want this to be an ordinary book; it is not. It will periodically delight, interest and infuriate its readers; but these seem to be characteristics of the books that prove most formative to their subjects and I think time will show this book to be important.

#### Of mites and models

The Functional Response to Prey Density in an Acarine System. (Simulation Monographs.) By H. G. Fransz. Pp. viii+143. (Centre for Agricultural Publishing and Documentation: Wageningen, 1974.) Dfl.20.

DURING the last few years ecological theory seems to have outpaced the collection of ecological data. Professor Maynard Smith's book Models in Ecology (Cambridge University Press, 1974) showed amply that models can be formulated and built, but that their testing on real data and validation by prediction in the real world is still not possible because of a shortage of data. It was with these thoughts in mind that I welcomed Fransz's book which describes systems whereby the mite Typhlodromus occidentalis preys on various stages of another mite Tetranychus urticae. The book combines the observational approach to this predatorprev system with model building and validation by comparison with experimental results.

The first two chapters provide an introduction to the experimental system and the variables that the author measured (prey density, hunger, locomotion velocity and so on), and the third chapter describes the results of

# **ULTRAMICROSCOPY**

a journal devoted to the technical and theoretical advancement of structural research

Scope of the journal

A quarterly publication committed to the advancement of the tools and methods for the microscopic determination of ultrastructures. Its interdisciplinary content will cover all aspectsfundamental and technical--pertaining to the advancement of the state of the art, including, with the exception of light, all manner of radiation and the utilization of new principles.

It is the intent of this journal to provide a synopsis so that the researchers in biology and materials science whose primary interest is the investigation of specific structures can readily seek and find the most current developments in ultramicroscopy, thus bridging the gap in communication between the developer and user.

To this end, the original communications, comprehensive reviews, short notes, letters and reports will be published rapidly, with high quality reproduction of half-tone pictures assured.

#### Invitation to authors

The editor cordially invites his colleagues to submit papers to his address for publication in "Ultramicroscopy". All papers are subject to refereeing. The journal will not carry a page-charge. A brochure containing detailed instructions to authors is available on request from the editor and the publisher.

E. ZEITLER. The Enrico Fermi Institute of the University of Chicago, 5630 Eliss Avenue, Chicago, 111. 60637, U.S.A.

#### Preliminary editorial advisory board:

experiments that measured these variables. Multiple regression analysis, apparently without significance tests, is frequently used to relate the different variables. The fourth chapter is concerned with building models, and the final chapter compares the output of models with the experimental data, demonstrating that stochastic models generally give a better fit to data than deterministic models.

The book does achieve the objective of building and testing models, but its style closely resembles the thesis that it is. The use of Fortran-type variables throughout the text and in tables and figures makes the book difficult to read, necessitating continual reference to Appendix IV where one needs to look up the root variable name as well as prefixes and suffixes. The information in the book is diffuse and space is wasted with unnecessary simple computer programmes and procedures. The essential points of model building and of testing on experimental data could have been written much more concisely, and probably with more effect, as an article in a journal.

#### **Drugs and toxins**

The Chemistry, Metabolism of Drugs and Toxins: An introduction to Xenobiochemistry. By Michael and Maxine Briggs. Pp. xii+386. (Heinemann Medical: London, June 1974.) £5.00.

This pot-pourri of data from chemistry, biochemistry, biochemical pharmacology, pharmacology and toxicology is put together in four chapters entitled, respectively, Metabolism of foreign compounds, Biochemistry of drugs, Natural antimetabolites, and Venoms. It is given the sub-title "Xenobiochemistry" which is not new (see Nature, 187, 94; 1960). The first chapter contains a somewhat superficial account of drug metabolism and the second tries to cover the types, absorption, transport, elimination, mode of action and side effects of drugs, but has 50 pages of tables with several half-empty pages. The third chapter covers microbial toxins, antibodies and antimetabolites whereas the fourth is on the composition and action of all kinds of animal and plant venoms. The book has attempted to concentrate too much into too little and this results in some wrong impressions, as in the case of thalidomide (p. 192) which is known to undergo spontaneous hydrolysis in vivo and in vitro rather than the enzymic metabolism implied by the book. The chapters on antimetabolites and venoms are, however, useful introductions to the study of these toxins.

(Continued from page 128)

eluted the agglutinin with D-galactose (ref. 22 and details to be published). Based on specific agglutination titre a 75-fold purification with 50% recovery was achieved. Since the product was pure by electrophoretic criteria (Fig. 2) this result indicates that the agglutinin constitutes approximately 1% of the total extractable protein in cohesive P. pallidum cells. The subunit molecular weight of the P. pallidum protein is estimated to be about 25,000 (Fig. 2) as compared with 26,000 for discoidin11; its isoelectric point is 7.0 (details to be published) whereas the value is 6.1 for discoidin11. The two agglutinins also differed in their interaction with a wide range of sugars (Table 1). For discoidin, the most potent inhibitors were N-acetyl-D-galactosamine and 3-O-methyl D-glucose. In contrast, the P. pallidum agglutinin required 15 times as much of the former and 60 times as much of the latter for comparable inhibition but was eight times more sensitive to lactose and four times more sensitive to D-galactose.

Since the protein agglutinated erythrocytes we determined if it also agglutinated *P. pallidum* cells. To test this we added the pure protein to cohesive *P. pallidum* cells which had been

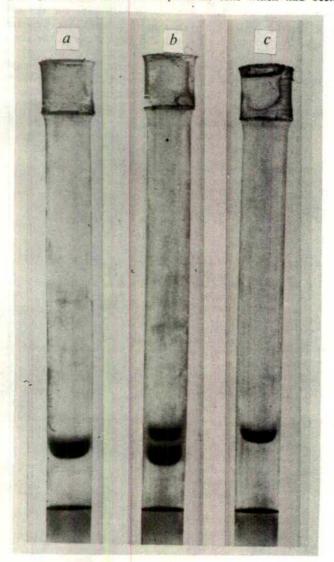

Fig. 2 Polyacrylamide gel electrophoresis of purified agglutinins from *P. pallidum* and *D. discoideum*. Approximately 25 μg of each protein was applied to a discontinuous sodium dodecyl sulphate (SDS)-polyacrylamide system<sup>23</sup> with a 3% acrylamide stacking gel and an 8.0% separating gel as described previously<sup>11</sup>. To assure complete solubilisation, samples were heated at 100° C for 5 min immediately before application to gels. Cytochrome *c* (5 μg) was added routinely to samples as a reference protein. The discoidin preparation and molecular weight calibration were as described previously<sup>11</sup>. *a*, *P. pallidum*; *b*, mixture; *c*, *D. discoideum*.

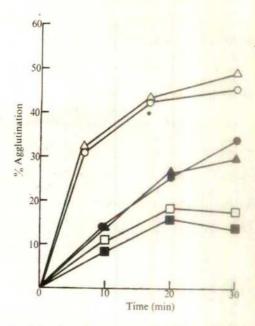

Fig. 3 Agglutination of heat-treated (60° C) *P. pallidum* cells by purified agglutinin. Cells were collected from 90-h plates, washed and suspended, 10° ml<sup>-1</sup>, in 16.7 mM Na<sub>2</sub>HPO<sub>4</sub>-KH<sub>2</sub>PO<sub>4</sub> (*p*H 6.0) buffer, and heated at 60° C for 10 min. Agglutinin was purified and then extensively dialysed against PBS. Since there was partial loss of activity, the concentration of active agglutinin was estimated on the basis of agglutination activity. Agglutination assays were done in plastic trays with 16 mm wells (Linbro cells ml<sup>-1</sup> plus one of the following sets of consisting of 2×10° cells ml<sup>-1</sup> plus one of the following sets of constituents: (Δ) PBS; (Δ) purified agglutinin (0.5 μg ml<sup>-1</sup>)+D-galactose (0.2 M); (□) purified agglutinin (0.5 μg ml<sup>-1</sup>)+D-glucose (0.2 M); (□) 0.2 M galactose; (♠) 0.2 M D-glucose. A separate well was used for each time point. The tray was gyrated at 115 r.p.m. on a New Brunswick G-24 shaker (23° C). At 10 min intervals the contents of wells were carefully removed, diluted in 20 ml of saline and single cells were counted with a Coulter counter (100 μm aperture: 1/aperture current = 1/4; 1/amplitude=2; threshold=20-80. The percentage agglutination was expressed as the percentage of single cells that had disappeared relative to time 0 (ref. 24).

heated at 60° C for 10 min to reduce their endogenous agglutination (Fig. 3). Agglutination was assayed by measuring the disappearance of single cells in a gyrated suspension 24.2 The purified protein (0.5 µg ml<sup>-1</sup>) agglutinated the *P. pallidur* cells; and this agglutination was blocked by 0.2 M p-galactose but not by 0.2 M p-glucose (Fig. 3).

We next looked for agglutinin on the surface of cohesive cells. When erythrocytes and cohesive P. pallidum cells were mixed and shaken on a slide, large mixed clumps formed within a minute, consisting of slime mould cells in contact with one another and with erythrocytes. p-Galactose (0.15 M blocked formation of these clumps whereas p-glucose did not To test the possibility that erythrocytes were being agglutinate because of secretion or release of protein from the slime mould cells, we maintained cells in medium for 10 min, then sputhem out, and tested the supernatant for erythrocyte agglutination activity. Since no agglutination was observed, this suggested that the agglutinin is not secreted and is therefor present on the surface of the slime mould cells.

In view of this finding we investigated whether the saccharide that interact with this protein blocked the endogenous cohesive ness of the slime mould cells. In a previous experiment (Fig. 3 we found that cells heated to 60° C for 10 min retained som cohesiveness. With a milder heat treatment (51° C for 10 min the cells were significantly more cohesive. (It should be note that purified factor retained about 50% of its erythrocyt agglutination activity when heated under these conditions. Determining agglutination by measuring the disappearance of single cells, we examined the effects of several sugars on this residual cohesiveness. D-Galactose and lactose were effective

% Inhibition of agglutination

inhibitors down to 6 mM whereas p-glucose and p-mannose were effective only at 500 mM (Fig. 4a). When living, untreated P. pallidum cells were used, differential sugar inhibition of cohesiveness was again observed (Fig. 4b and c); but compared with the results with heat-treated cells, the concentrations of sugars required for differential inhibition were about 15 times higher. The difference between heat treated and living cells may be due to (a) more functional agglutinin in living cells; (b) higher binding affinity between agglutinin and its receptor in living cells; or (c) secondary adjunct binding sites in living cells.

Our findings support a role for the carbohydrate-binding protein in intercellular adhesion in P. pallidum, although its participation in other differentiative processes should be

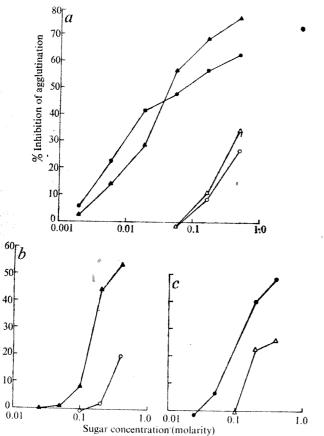

Fig. 4 Effect of sugars on agglutination of heat-treated (51° C) (a) or normal (b, and c) P. pallidum cells. a, Cells from 90 h plates were suspended at 10<sup>7</sup> ml<sup>-1</sup> in 16.7 mM Na<sub>2</sub>HPO<sub>4</sub>-KH<sub>2</sub>PO<sub>4</sub> pH 6.0, buffer and heated at 51° C for 10 min. The cells were then washed and dispersed in the same buffer. Each well of the Linbro tray contained 2×10<sup>6</sup> cells ml<sup>-1</sup> plus PBS buffer containing the indicated concentration of sugar (0.5 ml total volume) taining the indicated concentration of sugar (0.5 ml total volume). There were three replicate wells for each treatment. The plate was gyrated at 115 r.p.m. for 60 min, by which time agglutination had reached a plateau. The contents of each well were diluted and counted as in Fig. 3 to determine the percentage reduction in agglutination relative to controls containing no sugar. The selective inhibition of agglutination seen quantitatively in the figure was verified qualitatively by visual inspection (b and c). Cells were collected from 93-96 h plates. The cells were suspended and dispersed into EDTA-phosphate buffer (Fig. 1 legend). Each well of the Linbro tray contained  $3 \times 10^6$  cells ml<sup>-1</sup> plus EDTA-phosphate buffer or sugar in EDTA-phosphate buffer at different concentration (0.5 ml total volume). Galactose ( $\triangle$ ) and mannose  $(\bigcirc)$  were compared in one experiment (b) and lactose (lacktriangle) and glucose  $(\triangle)$  in the other (c). There were three 115 r.p.m. for 60 min, a period sufficient to attain equilibrium. The contents of each well were diluted into 20 ml of EDTA-phosphate buffer and single cells were counted (100 µm aperture; 1/aperture current=0.354, 1 A=1, thresholds=10-60). As above, the percentage reduction in agglutination was determined for each sugar. The selection counter of the sugar that for each sugar. The selective sugar effects were verified visually.

considered. Our working hypothesis is that this protein is a cell-ligand26 that binds slime mould amoebae together by attaching to carbohydrate-containing receptors on adjacent cells. The basis of the erythrocyte agglutination assay would derive from a structural resemblance between the erythrocyte surface oligosaccharides and the native slime mould receptor. Thus, under this model, there would be two principal components in the adhesion system: a multivalent carbohydratebinding protein which is a peripheral membrane protein<sup>27</sup> and a carbohydrate receptor possibly associated with an integral membrane component<sup>27</sup>. Carbohydrate-containing macromolecules have been implicated in cell adhesion in several other systems, including microbe-host cell interactions 18-30, mating reactions of bacteria<sup>31</sup>, yeast<sup>32</sup> and Chlamydomonas<sup>33</sup> and cell-cell interactions in tissue formation3,34-36.

Finally, we suggest that the difference in the carbohydratebinding specificities of the agglutinins from D. discoideum and P. pallidum may underlie the selective intercellular affinities exhibited by cells of these species 37-39. Further work is required to test our model for slime moulds and to determine its relevance in the analysis of specific cellular interactions in higher systems.

We thank Dr Danton O'Day for P. pallidum WS-320, John Kafka for helping to develop the cohesiveness assay and R. W. Reitherman for his aid and suggestions in the sugar inhibition studies. #### Cyclic expression of a growth conditioning factor (MGF) on the cell surface

THE cell surface has been implicated as a regulation site for cell division in various systems. Enzymatic alteration of the cell surface can initiate DNA synthesis in contact inhibited cells1-3 and changes in membrane components have been correlated with the expression of the transformed phenotype4-10 and with the entry into the S phase of normal cells11. We describe here a system in which the induction into DNA synthesis of a nondividing cell population is regulated by a factor exteriorised only during the S and mitosis periods at the surface of the producer cells.

Peritoneal macrophages can be maintained in vitro but do not proliferate; they can, however, be induced to synthesise DNA and divide in medium conditioned by cells of the same species12-14. In our system medium conditioned by L cells in logarithmic growth was used and tested on macrophages collected from the peritoneal cavities of starch-inoculated C57BL/6J mice as described previously13. The assays were performed in Lab-Tek four chamber slides seeded with 3.0  $\times$  10 $^{\rm 5}$  nucleated peritoneal cells per chamber. Thirty minutes after seeding, the cultures were washed twice with phosphate buffered saline (PBS) to remove unattached cells, and refed. After 2-3 d the desired concentration of samples was diluted in TES-HEPES-buffered Eagle's medium. pH 7.6 (ref. 15), with 10% foetal calf serum (FCS) and added to macrophages in the presence of 0.2 μCi ml<sup>-1</sup> <sup>3</sup>H-thymidine (dT) (specific activity, 52 Ci mmol<sup>-1</sup>). After 5 d the cells were fixed with Carnoy's solution and prepared for autoradiography.

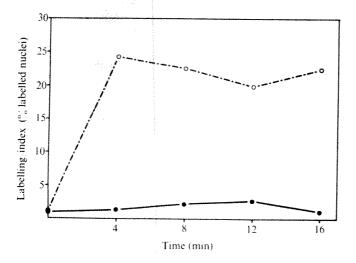

Fig. 1 Release of MGF with increasing time of trypsin treatment. Incubation of 2 ml of 0.1% trypsin (○---○) or medium alone (●--●) with duplicate milk dilution bottles of L cells previously washed twice with PBS. Reaction stopped with 10% FCS. All samples assayed in duplicate at a trypsin digest concentration of 40%. Assay was for 5 d with a continuous label of 0.2 μCi ml<sup>-1</sup> dT.

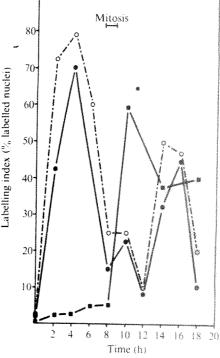

Fig. 2 Spontaneous and tryptic release of MGF from synchronised L cells. L cells seeded 24 h previously, 1 × 10° cells per 60 mm Petri dish were synchronised with 10 ° M dT as described. in the text. At different times after release, L cell coverslips were pulsed for 20 min with 2.0 µCi ml<sup>-1</sup> dT (specific activity 52 Ci mmol<sup>-1</sup>). Coverslips were fixed in Carnoy's solution for autoradiography. Cells were read for labelled nuclei ( times indicated duplicate L cell cultures were trypsinised with 0.1% trypsin for 5 min and the reaction was stopped with 10% FCS. Samples of medium incubated with the cells from the time and conditioned medium ( $\blacksquare - \blacksquare$ ) were assayed on macrophages at a concentration of 40% for 5 d with 0.2  $\mu$ Ci ml<sup>-1</sup>dT. Autoradiography was performed as described previously.

The presence of macrophage growth factor (MGF) not only in the conditioned medium, but also in cell lysates was demonstrated as follows. Suspensions of 4 × 10° L cells per ml were washed repeatedly and sonicated for 3 min at 30-s intervals. Dilutions of whole sonicates were assayed on macrophages for stimulatory activity. An increase in the concentration of crude cell lysates increased the number of labelled macrophages. To determine whether stimulation was specific, two mouse cell lines which do not produce active conditioned medium were sonicated and tested for activity: neither showed stimulatory activity in their lysates (data not shown).

To determine the cellular localisation of the MGF, L cells were treated with 0.1 % trypsin (Flow Laboratories) 24 h\*after plating at 37° C for periods of 0-16 min; trypsinisation was terminated with 10% FCS or soybean trypsin inhibitor. Samples were filtered through 0.22 nm filters to eliminate contaminating L cells. As Fig. 1 shows, maximal activity was released at 4 min; 0.05% purified trypsin (Worthington) released comparable amounts of activity (data not shown). No detectable MGF was released when cells were incubated with medium alone during the experimental period.

Since changes occur in the components of the cell surface during the cell cycle we investigated whether MGF was released by trypsin only during certain phases of the cycle. L cells were synchronised by a double dT block (10-3 M dT for 16 h, 6 h release, followed by another 16 h block). At 2 h after release, 70% of the cells were in the S phase as shown by autoradiography after a 20-s pulse with dT (Fig. 2), Mitosis (30%) followed 8 h after release; a second round of DNA synthesis followed 12 h after the first.

At different times in the cell cycle samples of medium were taken to test for spontaneously released MGF, and L cells were

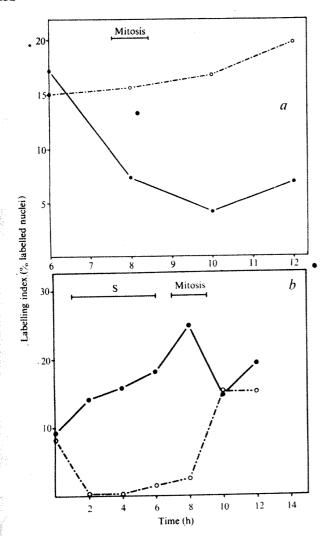

Fig. 3 a, Trypsin release of MGF in cells blocked during mitosis. L cells synchronised with a double dT block were released (time 0) and 5 h later blocked with 0.03 µg ml<sup>-1</sup> vinblastine sulphate (Velban, Lilly) (\(\circ\) - - \(\circ\)) or refed with medium alone (\(\bullet\)-\(\bullet\)). At the times shown, 5 min duplicate trypsin digests were taken. Samples were assayed at a concentration of 40° under standard conditions. b, MGF in lysates from synchronised L cells. L cells synchronised by a double dT block as described in the text were scraped from two 60-mm Petri dishes into 2 ml of TES-HEPES-buffered Eagle's medium (pH 7.6) with 10% FCS and sonicated for 30-s intervals totalling 3 min. ——, Points were taken every 2 h from time of release from dT. At the same times, sister cultures were trypsinised for 5 min (this did not remove cells from the glass). These cells were then treated similarly for sonication. Ο --- Ο, All sonicates were assayed at a concentration of 10% for 5 d in the continuous presence of 0.2 μCi ml<sup>-1</sup> dT. Slides were prepared for autoradiography as described previously.

trypsinised for 5 min with 0.1% trypsin at 37° C. Under these conditions, there was no alteration in cell morphology and viability remained at 95%. Figure 2 shows that MGF activity could be trypsin-released from cells only during the S phase, with almost no activity recoverable when DNA synthesis stopped; activity reappeared again at the next S phase. The spontaneously released MGF appeared in the medium as the activity disappeared from the surface.

It was not clear in these experiments whether MGF was released before or after mitosis. To resolve this, L cells were synchronised with a double dT block, then released, and 5 h later, in the middle of S phase, arrested with 0.03 g ml<sup>-1</sup> of vinblastine sulphate. In the control cells, as expected, no MGF was released by trypsin during G1; in the cells blocked in mitosis instead, MGF could be released as late as 12 h after removal of the dT block (Fig. 3a). It seemed therefore that MGF remained associated with the cell surface in cells blocked at mitosis.

The above results indicated cell cycle dependency for the presence of MGF in the trypsin-releasable material both at the cell surface and in the medium. To understand better the dynamics of the distribution of MGF during the cycle, localisation in the whole cell lysate was compared with that remaining in the cells after trypsin treatment. Parallel cultures were synchronised as before. MGF was assayed in the whole lysate from cultures previously treated with trypsin or untreated. All points were taken from duplicate assays of lysates from two 60-mm Petri dishes each containing  $3 \times 10^6$  to  $4 \times 10^6$  L cells. Figure 3b shows that MGF activity was present in cell lysates at all times in the cell cycle. Trypsinisation of the cells before sonication eliminated activity in lysates only during S and mitosis, confirming previous results with trypsin digests.

On the basis of the results of this study, the following interpretation can be made: (1) MGF is present and presumably synthesised at all times in the cell cycle; the buildup of activity seen before transfer to the surface and release supports this. (2) MGF is transferred to the surface during S phase, where it remains until after metaphase when it is released into the medium.

Previous work in our laboratory has shown that MGF present in L cell-conditioned medium was stable to various enzymes and treatments, but was destroyed by periodate and by subjection to  $100^{\circ}$  C for 10 min (ref. 12). These studies indicate that the active moiety contains carbohydrate. This agrees with evidence that trypsin releases glycopeptides from the surface of plasma membranes (for a review see ref. 22). The mode of synthesis and transfer of this factor as described here is in accord with the model of synthesis of glycoproteins proposed by Schachter and Roden<sup>16</sup>. These authors reported that glycoproteins are synthesised intracellularly on polyribosomes and as glycoproteins transported through the Golgi apparatus to the cell periphery16. Several growth regulatory factors have been isolated and identified as glycoproteins, attesting to the significance of this class of molecules in the control of cell proliferation17-20.

This work was supported in part by grants from the American Canter Society, the National Cancer Institute and the National Institute of General Medical Sciences.

A vertical rotation mixing machine, designed to mix fluids by a tumbling action around a horizontal axis and suitable for use in incubators or hot rooms, as well as at room temperature. The machine accommodates a wide range of stoppered glass test tubes in interchangeable fittings firmly retaining the stoppers.

Mixing is effected by continual inversion of the containers at speeds continuously variable between 10 and 100 r.p.m., enabling the operator to select the optimum mixing action to suit individual requirements. The degree of control is such that the machine is equally suitable for emulsifying and avoiding, or at least minimising, emulsion formation for such techniques

as solvent extraction, whilst maintaining efficient mixing, · even with considerable differences in relative densities of fluids.

Since mixing action depends largely on the difference in density of the phases in solvent extraction it is possible to mix efficiently with no air space in the container, any tendency to emulsion formation being reduced as the air space is reduced and correspondingly increased as the air space is increased.

Volume 5 Chemistry and Chemical Technology: Part 2 Spagyrical Discovery and Invention: Magisteries of Gold and Immortality

#### JOSEPH NEEDHAM

The fifth volume of Dr Needham's immense undertaking, like the fourth, is subdivided into parts for ease of presentation and assimilation, each part bound and published separately. The volume as a whole covers the subjects of alchemy, early chemistry, and chemical technology (which includes military invention, especially gunpowder; paper and printing; textiles; mining and metallurgy; the salt industry and ceramics).

#### Foraminifera Volume 1

edited by R. H. Hedley and C. G. Adams October 1974, viii+278 pp., £5.80/\$15.00

0.12.336401.9

This volume is the first of an open-ended series devoted to substantial review articles on different aspects of foraminiferal research, such as biogeography, biometrics, cytology, ecology,, oceanography, sedimentology, stratigraphy and systematics, its purpose is to provide specialists and general readers alike with up-to-date surveys of resarch, in which critical evaluation is combined with clear presentation. The series will be of interest to industrial and academic palaeontologists, zoologists, geologists and all who wish to know how specialized non-biological techniques have been applied to Foraminiferal and how foraminiferal studies have advanced other fields of research.

Society for Applied Bacteriology Symposium Series No. 3

#### The Normal Microbial Flora of Man

edited by F. A. Skinner and J. G. Carr

September 1974 xvi+264 pp., £6.00/\$15.50

0.12.648040.0

The papers in this volume are by leading specialists in their fields and give especial consideration to three microbial habitats; the skin, mouth and intestine. For each of these systems contributors have attempted to characterize the normal microflora and to determine changes in its composition in response to intrinsic regulatory mechanisms or to antimicrobial agents. In order to give a comprehensive view of the subject, further, single, contributions cover such topics as the microflora of the vagina, dental plaque, dispersal of micro-organisms from the respiratory tract and viruses in the healthy subject.

#### The Histology of the Fowl

R. D. Hodges

October 1974, xvi+648 pp. £13.50/\$35.00

0.12.351350.2

Conceived originally as a laboratory manual, this volume emerges as a full-size reference work, its depth of coverage justified by the absence of any comparable book on the subject. In a few places the author found it necessary to supplement the text with references to other avian species, but as far as possible he has limited his scope to the fowl, since it is on this species that a very large proportion of the research work on birds is being carried out.

#### Iron in Biochemistry and Medicine

edited by A. Jacobs and M. Worwood

October 1974, xiv+770 pp., £15.20/\$39.25

0.12.379150.2

This book is a contribution towards an interchange of information between all scientists interested in iron metabolism whether they are primarily involved with biochemical, medical or nutritional problems. It emphasizes human studies, but much of the experimental work described is in other species. There is a chapter on genetic abnormalities in animals which may provide suitable models for the study of disorders of iron metabolism. This work breaks new ground in being the first multidisciplinary book on iron metabolism and the combination of current thoughts in the fields of biochemistry, nutrition, pathology and clinical medicine will be stimulating to readers in all these disciplines.

#### An electrophysiological study of the hippocampus of the 'reeler' mutant mouse

THE laminar organisation of neurones in the brain of the homozygous 'reeler' mutant mouse1 is grossly disrupted, especially in the cerebellum, hippocampus and neocortex2-6. Although a number of histological studies on synaptic organisation in the cerebellum of various mutants have been reported7-9, the effect of such disorganisation on interneuronal connections has not been investigated electrophysiologically, either in the cerebellum or elsewhere.

Here we report evidence which suggests that there is a high safety factor in the developmental processes responsible for ensuring orderly synaptic organisation. Despite the cellular disarray in the hippocampus of the homozygous reeler, the resultant synaptic organisation as revealed by electrophysiological techniques is essentially normal.

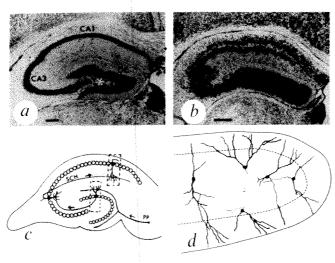

Fig. 1 Anatomy of normal and reeler hippocampus. Transverse sections through the hippocampal formation of 18-d-old normal (a) and 'reeler' (b) littermates. Cresyl fast violet stain. Asterisk indicates the hilus of the dentate area. CA1 and CA3, pyramidal cell fields CA1 and CA3 of Lorente de Nó (1934); GC, granule cells. Bars in a and b denote 200 µm. c, Diagram of the main excitatory pathways in the hippocampal formation. Arrows give the direction of impulse traffic. Dashed rectangles represent approximate regions of the hippocampal formation from which the data of Figs 2 and 3 were obtained. PP: perforant path; SCH: Schaffer collaterals, d, Composite camera lucida drawing of granule cells in the dentate area of 'reeler' mice, impregnated by the rapid Golgi method. Dashed outline indicates the boundary of the region occupied by granule cell bodies. Bar denotes 100 µm.

The extent of the defective alignment of cells in the hippocampus is shown in Fig. 1. In the normal animal both the pyramidal cells of regions CA3 and CA1 and the granule cells of the dentate area are arranged in tightly packed layers. In the reeler, the rigid layering of cells seen in the normal animal is absent; pyramidal cells are loosely packed, with occasional discontinuities and in region CA1 form two distinct layers, while granule cells are scattered widely throughout the hilar region of the dentate area.

The synaptic organisation of the normal hippocampus has been studied both histologically<sup>10</sup> and electrophysiologically<sup>11, 12</sup>. The axons of the perforant path (PP in Fig. 1c), the main input

to the hippocampal formation, form en passant synaptic contacts with the dendrites of granule cells. Pyramidal cells in region CA3 of the hippocampus, to which axons of the granule cells project, extend myelinated Schaffer collaterals (SCH in Fig. 1c) to the apical dendrites of pyramidal cells in region CAL

We have investigated the synaptic organisation of the perforant path and Schaffer collateral systems in reeler using the technique of field potential analysis. Wild-type or heterozygous littermates were used as controls.

When the perforant path of the normal animal is electrically stimulated, the synchronous depolarisation of the granule cel dendrites results in an inward flow of membrane current in the synaptic region; this inward current is passively extruded from the unactivated regions of the cell population, principally from the cell body layer. With an extracellular electrode, the distribution of membrane current is reflected as a negative potential in the region of the active current sink, reversing to a positive potential as the electrode approaches the cell body layer. A curve conventionally referred to as the 'depth profile of the response can be obtained by plotting the amplitude of the

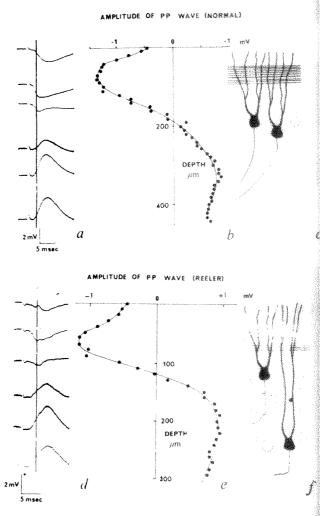

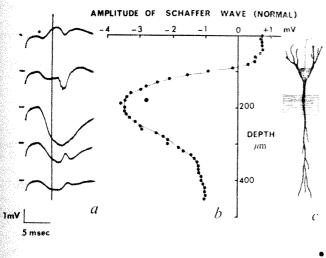

Fig. 2 Depth profiles of the perforant path (PP) wave in normal (a-c) and reeler (d-f) littermates. Samples of the synaptic waveforms are displayed on the left (a, d); the position of the baseline corresponds to the depth at which each potential was obtained. The amplitude of the evoked waveform, at a fixed latency (solid vertical line in a, d), is plotted as a function of depth in b and e. Zero depth was taken arbitrarily as 70  $\mu$ m above the point of maximum negativity, corresponding approximately to the hippocampal fissure. A spot of dye was ionto-phoretically ejected from the recording electrode at the end of each experiment. This gave a reference point enabling the position of the cell bodies to be accurately aligned with the corresponding depth profile (c, f). All animals were aged between 18 and 21 d and were anaesthetised with Equithesin.

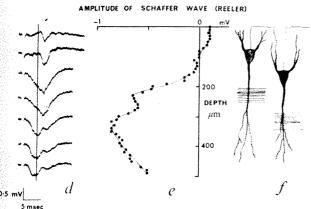

Fig. 3 Depth profiles of Schaffer waves in normal (a-c) and reeler (d-f) littermates. Samples of waveforms elicited by stimulating the Schaffer collaterals are displayed in a and d. The amplitude of the evoked waveform at a fixed latency (solid vertical line) is plotted as a function of depth from the hippocampal surface (b and e). The relative positions of the pyramidal cell population and Schaffer fibres are illustrated in c and f.

evoked potential, at a fixed latency, as a function of depth. In Fig. 2b, a profile of this type, obtained by stimulating the perforant path in a normal mouse, is plotted together with epresentative responses at various depths (Fig. 2a). The elative position of the granule cells is illustrated diagramnatically in Fig. 2c.

The depth profile of the perforant path response in the eeler (Fig. 2e) is essentially similar to that seen in the normal enimal. As in the normal, the evoked potential is negative in the molecular layer, superficial to the region of scattered granule tells, and its polarity reverses as the electrode advances to the ell body region. This result, which was consistently obtained in eelers, shows that perforant path terminals occupy the same osition in the reeler as they do in the normal animal. Two additional lines of evidence indicate that displaced granule ells establish synaptic contact with the perforant path by extending their dendrites into the molecular layer. First, ecords were obtained from single cells in the dentate area; in eelers, cells responding to stimulation of the perforant path ould be found throughout the hilar region, whereas in normal mice such neurones were confined to the granule layer. Secondy, we compared Golgi impregnated material in normal and celer mice. In the normal animal, granule cells were restricted the granule layer; in reeler, granule cells were frequently een in the hilus, with abnormally elongated dendritic arborisaions, sometimes extending into both upper and lower blades of the molecular layer (Fig. 1d).

Pyramidal cells of region CA1 were activated by stimulation of the Schaffer collaterals. In the normal animal, the peak of the

synaptic region occurs approximately  $100~\mu m$  below the pyramidal layer (Fig. 3b, c). In reeler, the pyramidal cell layer is split into two sublayers, separated by  $100~\mu m$  (Figs 1b~and~3f). The depth profiles obtained from reelers contained a double peak (Fig. 3e), showing that Schaffer collaterals form synaptic contacts with the dendritic shafts of pyramidal cells in two distinct layers, separated by the same distance as the cell body layers. This suggests that a different mechanism is at work in maintaining the integrity of the Schaffer projection from that discussed above for the perforant path. Instead of the post-synaptic cells extending their dendrites, the afferent fibres adjust their course to innervate the appropriate dendritic section of the displaced cells, either by means of a diversion of part of the Schaffer bundle to lower than normal depths, or by collateral sprouting.

The development of the hippocampus involves a number of events occurring in sequence. Autoradiographic analysis13 has shown that pyramidal cells are generated mainly between the 12th and 15th day prenatally, while granule cells mitose from the 16th prenatal day until the end of the third postnatal week. From the germinal layer, neurones migrate to their eventual destination and form laminar aggregates before making functional connections between one neurone population and another. In the rat, synaptic connections reach adult levels of efficacy by the end of the third postnatal week<sup>14</sup>. The events which lead to cellular disarray in the reeler brain presumably occur during, or subsequent to cell migration<sup>15</sup>. The site of the primary lesion of mutant gene action is not known; for example the migrating cells may be deprived of a genetic instruction to reach a given site, or they may be devoid of a surface property which facilitates aggregation once they have arrived; cortical cells cultured in vitro from reeler mice do not aggregate to form the laminar arrays characteristic of cells from normal littermates16.17.

Our present findings show that in reeler mice, orderly synaptic connections can be made between neurone populations in the hippocampus in spite of a genetic lesion affecting a prior developmental stage. When a granule cell is displaced in the hilar region of the dentate area, the dendritic tree of the cell is extended to the region traversed by the perforant path fibres. This suggests that the dendrites of displaced cells continue to grow until specified synaptic contacts are made. An alternative kind of adjustment to spatial disorganisation is seen in region CA1, where malpositioned pyramidal cells receive a normal Schaffer input. Analysis of the depth profiles suggests that a segment of the dendritic shaft at a given distance from the cell body has a high affinity for Schaffer fibres, and that when these segments are misaligned, afferent fibres are diverted, or form collaterals, to make synaptic junctions with the appropriate region of the postsynaptic cell. Thus, there is a high safety factor in the overall developmental programme for the hippocampus which ensures that the effects of a previous error are minimised.

We thank Dr R. Victoria Stirling for preparing the Golgi material and M. L. Errington and Maria Utting for technical assistance.

#### Different spike mechanisms in axon and soma of molluscan neurone

STUDIES with a few invertebrate preparations have suggested different ionic mechanisms for spike generation in the soma and axon of the same neurone. Iwasaki and Satowi found that somatic spikes in the crayfish eyestalk X organ had a mixed Na-Ca dependency, while the extracellular axon spikes disappeared in Na-free or tetrodotoxin (TTX)-containing solutions. Wald<sup>2</sup> recorded attenuated axon spikes in hyperpolarised somata of snail ganglion cells and showed that they varied in amplitude with external sodium concentration but, curiously, were not blocked by TTX. In voltage-clamp experiments with the left pleural giant cell in Aplysia, Kado<sup>3</sup> found that early inward currents in the axon-hillock region were much more sensitive to TTX than early inward currents in the opposite end of the soma, suggesting a greater Na-dependency of the axon spike.

In none of these studies, however, were action potentials recorded with intracellular electrodes in the axon at a large distance from the cell soma. We have been able to record from the axon of the right giant (R2) cell in the visceral ganglion of Aplysia at a distance of 3-4 cm from the soma. Our measurements indicate that the axon length constant is about 1 cm, so the axonal and somatic recording sites are electrically remote. This direct recording technique confirms that the axon spike is mainly sodium dependent, while the somatic spike has both sodium and calcium components4-6.

In all experiments the visceral ganglion together with the right (dorsal view) visceropleural connective was dissected from the animal and placed in a small-volume recording chamber containing normal saline. The preparation was then treated with a 1% solution of pronase (Calbiochem) in normal saline for 15-20 min to facilitate impalement through the epineurium. The microelectrodes used had resistances from 3-8 M $\Omega$ . Standard intracellular recording techniques were used, and all experiments were performed at room temperature.

The R2 axon is visually indistinguishable from the other axons in the connective because of its small diameter (35 µm) and lack of pigmentation7. Thus, we usually identified the axon by stimulating the soma with regular (1 s<sup>-1</sup>) pulses while searching across the right connective with a recording electrode at least 3 cm distal to the soma. Identification of the axon was made when both a 40-60 mV resting potential and 70-90 mV spike with a constant delay after the somatic spike were recorded with the axon electrode. The conduction velocity from soma to axon was typically 1 m s<sup>-1</sup>. In some experiments, stimuli were applied to the right connective with a suction electrode. This method was more convenient than attempting to place a second intracellular stimulating electrode in the axon. The suction electrode also enabled us to depolarise the axon more than was possible with a subtracting circuit for stimulating through the recording

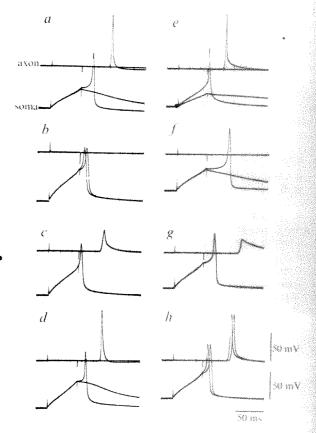

Fig. 1 Responses to somatic stimulation measured in soma and axon at 3 cm from soma. Two sweeps superimposed in most pictures. a, Normal saline; b, Na-free (Tris) solution; c, 2 min after perfusion with normal saline again; d, normal saline, 5 min later; e, normal saline; f, Na-free, Ca 340 mM; g, 2 min after perfusion with normal saline again; h, normal saline, 5 min later. All data from the same cell.

electrode. The R2 cell axon was apparently the only one from which we could record intracellularly, as no smaller spikes of large variations of conduction velocity were seen with antidromic stimulation.

Solution changes were made by perfusing about 40× 11 chamber volume of each solution. The normal saline used has the composition: NaCl 494 mM, KCl 11 mM, CaCls 11 mN MgCl<sub>2</sub> 19 mM, MgSO<sub>4</sub> 30 mM, Tris-HCl (pH 7.7) 10 mM Sodium-free saline had the same composition except that 5 mM neutralised Tris was substituted for sodium. High-calcium saline was made by replacing the NaCl with 340 mM CaCl, an substituting MgSO<sub>4</sub> with MgCl<sub>2</sub> to prevent precipitation of CaSO<sub>4</sub>.

The mixed Na-Ca dependency of the somatic action potential in the R2 cell has been shown previously4-6. The ionic depend ency of the axon spike is compared with that of the somat spike in Fig. 1. The top trace in each part is the axon membrar potential measured at about 3 cm from the soma, and the bottom trace is the somatic membrane potential. Depolarising stimu were applied to the soma through a second intracellula electrode. Figure 1a was obtained in normal saline, and show two superimposed sweeps, one in which the stimulus was su threshold, and one in which it was suprathreshold. The axon spil was 87 mV, and the somatic spike was 93 mV, measured from resting. Figure 1b shows the blockage of the axon spike which was seen after about 2 min in Na-free (Tris) medium, while the somatic spike was still 88 mV, measured from resting; Figure was taken after the start of perfusion with normal saline agai and shows a partial recovery of the axon spike and Figure shows the final recovery of the axon spike to 88 mV, measure from resting.

To further test the axon's dependency on sodium we treate the preparation with 30 µM tetrodotoxin (TTX: Calbiochem

TTX has been shown to block selectively the active sodium conductance in a number of excitable membranes8, and would be expected to block the axon spike if it were mainly dependent on sodium. After 10-15 min, TTX completely and reversibly blocked the axon spike in response to somatic stimulation, while having little effect on the soma spike.

If the axon membrane has a calcium channel like that in the soma, then it should be possible to produce axon spikes in a solution in which all the sodium is replaced with calcium (the somatic action potential is larger in such a solution than in normalsaline). Figure 1e-h, shows that we could not produce axon spikes in high-Ca solution by somatic stimulation. Figure 1e was obtained in normal saline, and shows two superimposed sweeps, one with a subthreshold stimulus. Figure 1f shows the blockage of the axon spike after about 2 min in Na-free, Ca 340 mM solution, while the soma spike was 108 mV. Figure 1g shows a partial recovery after the start of perfusion with normal saline, and Figure 1h shows the amount of recovery about 5 min

These experiments demonstrated that the axon could not conduct action potentials in Na-free solutions or in the presence of TTX. It was possible, however, that the axon membrane might still be excitable in Na-free solution, if a depolarising stimulus were applied close enough to the recording area to affect it directly. To test this possibility we stimulated the axon through a suction electrode applied to the cut end of the right connective. with a chlorided silver wire just outside the end of the electrode serving as the return path for the current. The recording electrode was placed in the axon at about 0.5 cm from the suction electrode. With this method of stimulation the axon spike was again blocked by replacement of external sodium with Tris. Within 5 min after perfusion with Na-free solution, depolarisations of up to 30 mV produced no regenerative response. Partial recovery of the spike was seen upon reperfusion with normal saline. The antidromic axon spike was also blocked by 30 µM tetrodotoxin in the external solution. To test the possibility that the axon membrane might have a calcium channel like that in the soma, we repeated the high-calcium experiment shown in Fig. 1e-h, with direct axonal stimulation using a suction electrode. Replacement of external sodium with calcium completely blocked the axon spike within 5 min. This experiment indicated that, when external sodium was replaced with Tris or calcium, the R2 axon was not only incapable of conduction, but was also inexcitable even with direct stimulation.

The absence of an axon spike in Na-free solution when the soma was stimulated (Fig. 1b and f) could have been due to conduction block in the axon. The partial spike seen upon reperfusion with normal saline (Fig. 1c and g), however, indicated that the amplitude of the axon spike when present was strongly dependent on external sodium. The blockage of the axon spike when external sodium was replaced with calcium showed that the axon membrane does not have a specialised calcium channel like the soma4-6. In addition these experiments suggested that no large calcium current goes through the axonal sodium channel during the action potential9.

#### Regulation of catecholamine synthesis in the rat brain in vitro by cyclic AMP

EVIDENCE that catecholamines stimulate the production of adenosine cyclic-3',5'-monophosphate (cyclic AMP) in the pineal gland<sup>1</sup>, superior cervical ganglia<sup>2</sup> and both in brain slices3,4 and homogenates5 has suggested that cyclic AMP has an important postsynaptic function in both peripheral and central adrenergic neurotransmission. Evidence has also been presented in the hypogastric nerve-vas deferens preparation<sup>6</sup> and adrenal medulla7 that dibutyryl cyclic AMP increases the release of noradrenaline, suggesting a presynaptic role for cyclic AMP in modulating catecholamine metabolism in adrenergic terminals. In the central nervous system, adenylate cyclase and phosphodiesterase are, to a considerable extent, associated with the isolated nerve-ending (synaptosomal) fraction<sup>8</sup> in which putative neurotransmitters are primarily localised. Thus it was of interest to determine whether cyclic AMP might also stimulate catecholamine turnover in the brain, especially in synaptosomes prepared from brain homogenates.

Recent experimental evidence demonstrates that dibutyryl cyclic AMP can increase the formation of dopamine from labelled tyrosine when incubated with brain slices9 or synaptosomes<sup>10,11</sup> prepared from the corpus striatum. We report here, a stimulation of tyrosine hydroxylase activity in rat-brain synaptosomes incubated with cyclic AMP derivatives; this effect can also be produced by cyclic AMP in a soluble preparation of tyrosine hydroxylase and is associated with changes in the kinetic parameters of tyrosine hydroxylation suggestive of an allosteric activation of the rate-limiting enzyme in catecholamine synthesis.

Tyrosine hydroxylase activity was assayed in crude synaptosomal fractions of rat striatal homogenates by a procedure (Table 1) which utilises the natural endogenous pteridine cofactor of tyrosine hydroxylase12. The rate of evolution of labelled CO<sub>2</sub> resulting from the decarboxylation of newly formed 14C-dopa was linear for at least 20 min and varied directly with the quantity of tissue present in the assay. The

Table 1 Effects of cyclic nucleotides on tyrosine hydroxylase activity in striatal homogenates

Compound added	% of control
	tyrosine hydroxylase activity $\pm$ s.e.m.

Monobutyryl cyclic AMP	$152 \pm 2*$
8-Methyl-thio-cyclic AMP	$136 \pm 4*$
Cyclic AMP†	79 + 3*
Dibutyryl cyclic GMP	84 1*
Na butyrate	99 主 3

Tyrosine hydroxylase activity was determined in a preparation of striatal synaptosomes<sup>12</sup> preincubated for 5 min in the presence or absence of cyclic nucleotides (1 mM) or Na butyrate (2 mM) and incubated for a further 20 min with a saturating concentration of 1- $^{14}$ C-L-tyrosine (20  $\mu$ M), in a Krebs-Ringer-phosphate medium at 37° C, pH 6.7. Mean control activity  $\pm$  s.e.m. = 20.3  $\pm$  0.3 nmol  $^{14}\text{CO}_2$  per g wet weight h<sup>-1</sup> and is represented as 100%. \*Significant difference by Student's t test (P < 0.01) of the difference

between enzyme activity in control compared with treated tissues for at least 9 to 12 experiments.

†In the presence or absence of theophylline (1.0 mM).

activity was stereospecific for the L-isomer of tyrosine and could be inhibited by low concentrations of 3-iodotyrosine or of dopamine, or pretreatment with intracranially administered 6-hydroxydopamine. Protein was determined by the method of Lowry et al.<sup>13</sup> with bovine serum albumin as a standard.

Table 1 shows that incubation of striatal homogenates with either dibutyryl or monobutyryl cyclic AMP, which are poor substrates for phosphodiesterase and to which membranes are relatively permeable, produced similar stimulation of activity, while cyclic AMP, which is less able to penetrate cell membranes14, produced a small inhibition, even when coincubated with the phosphodiesterase inhibitor theophylline (1 mM). Enhancement of the tyrosine hydroxylase activity was also found with 8-bromo-cyclic AMP and 8-methyl-thio-cyclic AMP, further suggesting that the stimulation might be mediated by the cyclic AMP moiety of these derivatives. The stimulation of tyrosine hydroxylase activity induced by dibutyryl cyclic AMP was not due to the butyrate moiety since incubation with sodium butyrate had no effect, and a small decrease was produced with dibutyryl cyclic GMP. The stimulatory effect of dibutyryl cyclic AMP did not occur distal to the tyrosine hydroxylation step since there was no alteration in the rate of formation of <sup>14</sup>CO<sub>2</sub> when carboxy-<sup>14</sup>C-D,L-dopa (0.1 mM) was substituted for tyrosine. When the concentration of dibutyry cyclic AMP in the incubation medium was altered, significant dose-dependent increases of tyrosine hydroxylase activity were observed, from 50 µM (about 14%) to a maximum (60%) at 1.0 mM of cyclic nucleotide when striatal synaptosomes were used. The hydroxylase activities in P2 synaptosomal fractions<sup>12,15</sup>, prepared from various brain regions were measured in the presence of dibutyryl cyclic AMP (1 mM); the hydroxylation of tyrosine was increased to a similar extent in striatal (57  $\pm$  3%) and cerebral cortical (51  $\pm$  2%) synaptosomes, and an even greater stimulation occurred in the brainstem (85  $\pm$ 4%). Thus, dibutyryl cyclic AMP seems to stimulate the rate of catecholamine synthesis in isolated nerve endings in several regions of the rat brain.

Table 2 Effects of cyclic AMP on the kinetic parameters of soluble, striatal tyrosine hydroxylase

	$K_m$ -DMPH <sub>4</sub>	$K_i$ -dopamine
Control Cyclic AMP (0.01 mM)†	$0.62 \pm 0.05 \\ 0.08 \pm 0.02*$	$(mM)$ $0.09 \pm 0.02$ $0.64 \pm 0.04*$

According to the assay procedure described in Fig. 1, the  $K_m$  for DMPH<sub>4</sub> was determined by the method of Lineweaver and Burke<sup>18</sup>, at a tyrosine concentration of 0.1 mM and six DMPH<sub>4</sub> concentrations ranging from  $10^{-5}$  to  $10^{-3}$  M. Each value is the mean  $\pm$  s.e.m. of the intercepts generated from six separate lines. The  $K_i$  was determined by the method of Dixon<sup>19</sup>, at three DMPH<sub>4</sub> concentrations of  $10^{-4}$ ,  $10^{-5}$ ,  $10^{-6}$  M, a constant L-tyrosine concentration of  $10^{-4}$  M and seven dopamine concentrations ranging from  $10^{-5}$  to  $10^{-3}$  M.

\*Indicates significant difference from controls at P < 0.01. †Cyclic AMP was added to the assay mixture 5 min before the initiation of the reaction by addition of substrate L-tyrosine.

Since cyclic AMP derivatives might cause an alteration in membrane permeability of neural tissues, we attempted to determine whether the observed stimulation of synthesis could be explained by an alteration of the uptake of substrate tyrosine into synaptosomes. This is probably not the case, since the uptake (0.5 to 20 min) of labelled tyrosine (20 µM) into striatal synaptosomes, selectively recovered on Millipore filters<sup>16</sup>, was not altered by incubating with dibutyryl cyclic AMP (up to 5 mM). Furthermore, in synaptosomes preincubated with dibutyryl cyclic AMP and subsequently washed, tyrosine hydroxylase activity was stimulated, even though the dibutyryl cyclic AMP was not present in the incubation medium. These findings suggest that the stimulation of tyrosine hydroxylase activity is not a result of an increased uptake of labelled precursor.

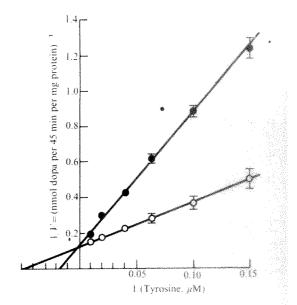

Fig. 1 Effect of cyclic AMP on the  $K_m$  for tyrosine of striat tyrosine hydroxylase. Soluble tyrosine hydroxylase activity w assayed in a 100,000g supernatant of striatal homogenates by modification of the method of Shiman et al. <sup>17</sup>. Tissues (50-70 protein) were pre-incubated for 5 min in the presence or absem of cyclic AMP (10  $\mu$ M) and incubated for a further 45 min 1.0 ml of medium containing: DMPH<sub>4</sub> (1 mM), sheep liveridine reductase, NADPH (1 mM), catalase (1,100 L sodium acetate buffer, pH 6.0, and various concentrations <sup>13</sup>H-3,5-L-tyrosine. Tyrosine hydroxylase activity was linear with time and protein concentration under the conditions used for the determination of  $K_m$ . Each value is the mean  $\pm$  s.e.m. of at least determinations. The lines drawn giving the best fit product an apparent  $K_m$  for tyrosine in cyclic AMP-treated tissues <sup>12</sup>22.3  $\pm$  2.7  $\mu$ M, which is significantly different (P < 0.01) frountreated controls of 53.6  $\pm$  3.9  $\mu$ M, with linear regressic coefficients r > 0.95.  $\bigcirc$ , 10  $\mu$ M cyclic AMP;  $\bigcirc$  control.

Another possibility would be a direct effect of cyclic A derivatives on tyrosine hydroxylase which could involve en an increased affinity for tyrosine or the pteridine cofactor, a decreased affinity for end-product catecholamines. We t investigated the effects of dibutyryl cyclic AMP and cyclic A on the activity of soluble tyrosine hydroxylase prepared fi the rat striatum in incubations which included a parti purified sheep liver pteridine reductase system<sup>27</sup> and subsatu ing concentrations of both 3, 5-3H-L-tyrosine (10 p and 2-amino-4-hydroxy-5,6,7,8-tetrahydropteridine (DMP) (0.1 mM). Activity of soluble tyrosine hydroxylase increased by about 40% and 57% with 0.1 mM dibuty cyclic AMP and cyclic AMP, respectively, while sodi butyrate had no effect. This activation was no longer evide however, when saturating concentrations of tyrosine a cofactor were used. By Lineweaver-Burke analysis18, apparent  $K_m$  for tyrosine was significantly decreased in presence of 10 µM cyclic AMP (Fig. 1) without any change  $V_{\text{max}}$ . Finally, when we applied Dixon kinetic analysis<sup>18</sup> seven-fold increase in the inhibitory constant  $(K_i)$  for dopam was observed with cyclic AMP (Table 2), suggesting a decrea affinity of soluble tyrosine hydroxylase for dopamine. In presence of cyclic AMP, a decrease in the  $K_m$  for DMP (Table 2) of seven to eightfold was also obtained withou significant change in  $V_{\text{max}}$ . A possible interpretation of the findings with soluble tyrosine hydroxylase is that cyclic Al produces an allosteric activation of striatal tyrosine hydroxyl which is mediated by increased affinities of the enzyme substrate (tyrosine) and cofactor and a decreased affinity for end-product inhibitor dopamine.

The significance of such a mechanism in the regulation catecholamine synthesis *in vivo* requires further investigation Cyclic AMP, however, may play a role in the activation tyrosine hydroxylase activity observed during increased activity

in both peripheral and central adrenergic neurones. Recent experiments have demonstrated that electrical stimulation of the guinea pig hypogastric nerve-vas deferens preparation<sup>20</sup>, as well as central dopaminergic21 and noradrenergic neurones22, causes an allosteric activation of tyrosine hydroxlase. This activation seems to be mediated by an increased affinity for both substrate and pteridine cofactor and a decreased affinity for end-product inhibitor<sup>20-22</sup> which is similar to that observed for cyclic AMP in the present experiments. In view of this theory and the observations that both electrical stimulation and depolarising agents can produce increased concentrations of cyclic AMP in brain slices23, one might postulate that cyclic AMP is partly responsible for an allosteric activation of tyrosine hydroxylase during neuronal depolarisation. Finally, the possibility that the mechanism underlying this allosteric effect involves activation of a cyclic AMP-dependent protein kinase and subsequent phosphorylation of tyrosine hydroxylase or some activator of this enzyme is under investigation.

#### Cadaverine in the brain of axenic mice

CADAVERINE has been shown to be present in the central nervous system (CNS) (refs 1, 2 and personal communication from M. Wiechmann). Its concentration in the whole brain varies during behavioural sleep in mammals and during hibernation in molluscs1.2. It is a precursor of piperidine, which has been linked with some functional stages of the CNS. Cadaverine is the source of much of the piperidine excreted in the urine3. Cadaverine has been considered a non-metabolite of the brain, and its presence in the body was believed to be due almost entirely to bacterial decarboxylation of lysine in the intestine4. In slices of mouse brain, exogenous cadaverine accumulates against a concentration gradient and can reach a concentration ten times greater in the tissue than in the surrounding medium4. The question has been therefore: does the cadaverine in the brain originate from an exogenous source; is it formed and resorbed in the intestine? Assaying cadaverine in axenic mice, we have now found that this is not the case, and that there is an endogenous source of cadaverine in the mouse.

Ten 3-month-old mice of each of the following strains were used: C57BL/6 (pathogen free colony of this department); •CD-1 COBS (Caesarean originated barrier sustained, Charles River), and CD-1 germ-free (Charles River). For the final 14 d, the CD-1 COBS mice were fed the same diet as the germfree stock. All animals were killed when active, that is moving in the cage, grooming and so on.

The mice were decapitated, the whole brain and blood samples were homogenised in perchloric acid, and the homogenate was dansylated and separated by thin-layer chromatography on silica gel. DANS-piperidine and bis-DANScadaverine TLC fractions were identified mass spectrometrically by their molecular ions (m/e 318 and m/e 568) and quantified by comparing their integrated ion currents with those of added internal standards of DANS-pyrrolidine (m/e 304) and bis-DANS-hexamethylenediamine (m/e 582) (for details and discussion of the method see refs 2 and 5).

Table 1 summarises our results. In all three groups of mice, cadaverine was found in both the brain and blood. The differences among individual mean values were not significant. The concentrations were measured as quantities more than 10 times higher than their blanks.

Table 1 Concentrations of cadaverine in the whole brain and blood of pathogen-free, COBS and germ-free mice

Mouse strain	Brain	Blood
C57BL/6	$0.30 \pm 0.07$ (7)	$0.24 \pm 0.07$ (7)
CD-1 COBS	$0.20\pm0.06$ (10)	$0.22 \pm 0.06$ (10)
CD-1 Axenic	$0.55 \pm 0.17$ (10)	$0.27 \pm 0.12$ (10)

Figures are in  $10^{-12}$  mol mg<sup>-1</sup> wet tissue, mean  $\pm$  standard error. The numbers of measurements are given in parentheses.

The different origins and environmental conditions of tested animals had no apparent effect on the concentrations of cadaverine in their brain and blood. The lack of microbial flora in the germ-free mice also had no apparent effect on their brain and blood cadaverine levels. In contrast, there was significantly more piperidine in the blood of COBS mice  $(1.10\pm0.23~{\rm pmol~mg^{-1}})$  than in that of germ-free mice  $(0.19\pm$ 0.05 pmol mg<sup>-1</sup>; P < 0.01). It seems therefore that the cadaverine concentration in both the brain and blood of active mice is kept constant, irrespective of the formation of cadaverine by bacteria in the intestine. The increased supply of exogenous cadaverine is compensated for by its conversion to piperidine, without allowing any appreciable increase in cadaverine in brain or blood.

From our findings we make the following conclusions. (1) There is a source of cadaverine in mice that is independent of the bacterial decarboxylation of lysine in the intestine; (2) both the blood and brain concentrations of cadaverine in active mice seem to be tightly controlled and are maintained at a level which does not depend on inflow of cadaverine from the intestine and (3) the concentration of cadaverine in the blood is probably maintained by the conversion of cadaverine into piperidine.

It seems therefore that there are two pools of cadaverine in mice. One provides both the blood and brain with an amount which might have some physiological importance which is unknown at present. The other pool, originating from bacterial decomposition of the food in the intestine, seems to be efficiently transformed into other compounds, one of them piperidine. and eliminated from the body.

There are indications that piperidine might be involved in functions of the central nervous system, particularly hibernation and sleep. Its concentration in the brain and blood varies during hibernation and behavioural sleep<sup>6-8</sup>, and it has relatively strong inhibitory effects on certain molluscan cholinergic neurones\*. Our results suggest that cadaverine in the brain and blood of mice could participate in this process.

It is interesting in this context that the so called 'pink spots' observed on chromatograms of the urine of schizophrenic patients were considered to be due to the presence of monoacetyl- and monopropionylcadaverine<sup>10</sup>. If our findings with axenic mice are relevant for humans, the presence of large amounts of anomalous metabolites of cadaverine in the urine could reflect not only the altered dietary conditions of schizophrenic patients as suggested10, but may also indicate a failure of the normal catabolism of cadaverine in their central nervous system.

#### Foetal origin of transferrin in mouse amniotic fluid

THE measurement of specific foetal products in amniotic fluid collected after amniocentesis offers an obvious approach to the foetus in utero. The proteins in mouse

amniotic fluid consist of three transferrins (Trf1, 2 at 3), five  $\alpha$  foetoproteins ( $\alpha$  FP 1-5) and albumins, the pr portions of which change during gestation1,3. The change in composition directly parallel those observed in foet serum, except that they occur 24 h later in the amnio fluid. No comparable alteration is observed in matern serum patterns. Transferrin 3 constitutes the major tran ferrin band both in late-stage foctuses and in adults, as so could be derived from either the foetus or the mothe We have investigated the origin of transerrin 3 in mou amniotic fluid, using a genetic difference at the transferr locus3 as a marker.

Reciprocal embryo transfers were made between inbr C3H/Bi/McL and randomly bred O-strain mice Blast cysts were flushed from donor uteri 3.5 d post coitum, at injected into the uteri of pseudopregnant recipients 2.5 post coitum4. Plasma was collected from donor females ( severing the carotid arteries) at transfer and from recipie females when autopsied on day 18 of gestation. Foetus were dissected from the uterus, with embryonic membran intact, and amniotic fluid sampled by insertion of 26-gauge needle directly into the amniotic cavity. Foet plasma was collected in heparinised capillary tubes fro an incision made in the external carotids. Fluids we analysed for protein on polyacrylamide slab gel electr phoresis'. Protein concentration was determined with the Lowry6 technique, using bovine serum albumin as standar

All Q donors and recipients proved to be Trfb/Trfb, at C3H Trf\*/Trf\*. Analyses were carried out on six C3 embryos on Q recipients, and three Q embryos in C3 recipients, and the transferrin type of the foetus provi in every case to resemble that of the donor strain (Fi 1A). Amniotic fluid transferring were identical in electrons phoretic mobility to those of the foetuses with which the were associated. Mixtures of plasma of recipient femal and transferred foetuses or their amniotic fluids resolve two Trf 3 bands, while mixtures of the donor plasm with foetal plasmas or amniotic fluids yielded one on (Fig. 1B), clearly demonstrating the foetal origin of the Trf 3 transferrin in the amniotic cavity.

Since Gustine and Zimmerman have already shown foetal origin of the five  $\alpha$  foetoproteins and Trfs 1 and our result indicates that all mouse amniotic fluid protein with the possible exception of the albumins, are of foet origin. The similarities between the protein patterns amniotic fluid and foetal plasmas, and the absence of mar maternal-type proteins in either fluid, support this. Th yolk sac, which is one site of  $\alpha$  foetoprotein synthesis completely surrounds the amnion in the mouse, and ma be important for transfer of the other proteins as well, not for their synthesis. The increase in sialyl transferal activity in the foetal liver coincides with the increase number of sialic acid residues in the foetal plasma foetoprotein, while the comparable changes in yolk sa sialyl transferase activity and in amniotic fluid a foet protein occur about one day later<sup>1,7</sup>. This suggests that the α foetoprotein in foetal plasma may be mainly derive from the foetal liver and the a foetoprotein in amniot fluid may be derived from the yolk sac.

The rapid changes in the volume and protein pattern of mouse amniotic fluid<sup>1,2,8</sup> may be related to the sho time spent in the uterus. Indeed, mouse amniotic flus perhaps by virtue of its proximity to the large and va cular yolk sac, has considerable similarities to marsupi yolk sac fluid, which is believed to play an important ro in foetal nutrition9, and in which, like the mouse amniot fluid, the transferrins are of foetal origin 16. Although the placental attachments are quite different in mice an marsupials, in both species the yolk sac prevents the amnion from making contact with the uterine lumen an maternal circulation, unlike in man, where the amnion in close contact with the uterine epithelium.

The obvious route by which a transferrin of foetal origin could pass into the amniotic cavity in mice is from the vitelline vessels across the exocoel and amniotic membrane (Fig. 2). It seems unlikely that transferrin proteins would diffuse from the foetal skin or alimentary canal into the amniotic cavity and the area around the umbilical stalk where the amnion is close to the allantoic vessels is small. In man, however, these other, perhaps less efficient, routes are the only ones available for transfer of foetal protein to the amniotic cavity, as the yolk sac remains small and rudimentary throughout development.

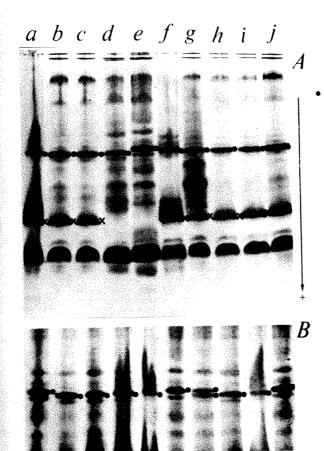

Fig. 1 Electropherogram of mouse plasmas and amniotic fluid. A, Replications A and B: C3H blastocysts (Trf\*/Trf\*) transferred to Q recipients (Trf\*/Trf\*). Wells from left to right: a, amniotic fluid; b, foetal plasma 1; c, foetal plasma 2; d, C3H donor plasma; e, Q recipient plasma; f, amniotic fluid; g, foetal plasma 1; h, foetal plasma 2; i, foetal plasma 3; j, foetal plasma 4. B, Mixtures of donor and recipient plasmas and amniotic fluid. Wells from left to right: a, recipient plasma Q (Trf\*/Trf\*); b, foetal plasma (C3H)+donor plasma (C3H); c, donor plasma C3H (Trf\*/Trf\*); d, amniotic fluid+donor plasma; e, amniotic fluid; f, recipient plasma; g, recipient+donor plasma; h, donor plasma; i, amniotic fluid; j, recipient plasma. Note that the only mix which yields two transferrins is that of donor and recipient plasmas: donor plasma mixed with its transferred recipient plasmas: donor plasma mixed with its transferred foetal plasma or amniotic fluid gives only one transferrin. Gels were run at 30 mA, 100 V for 2.5 h, and stained in 0.025% Coomassie Blue+0.1% Amido Black in 25% methanol and 7% acetic acid for 45 min. Destaining was by diffusion for 3 h in 25% methanol and 7% acetic acid in water. 25 µl of amniotic fluid (3 mg ml<sup>-1</sup>) and 2.5 µl of foetal plasma (20 mg ml<sup>-1</sup>) and maternal plasma (45 mg ml<sup>-1</sup>) were applied to each well. A tracking dye of bromophenol blue in 40% sucrose was used to colour the samples and show the boundary of the fastest moving components. The extra recipient plasmas: donor plasma mixed with its transferred the boundary of the fastest moving components. The extra bands visible in the  $\beta$  globulin region (between transferrin and a foctoprotein) in some samples are due to free haemo-globin and haemoglobin/haptoglobin (Hb/Hp) bands resulting from haemolysis of those plasmas during collection. •, Transferrin proteins;  $\times$ ,  $\alpha$  foetoproteins.

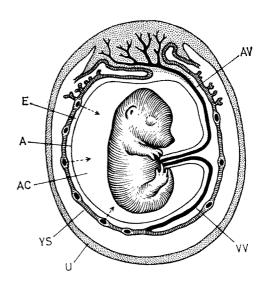

Fig. 2 The arrangement of foetal membranes in the mouse on day 15 of gestation, showing the likely route of transfer (arrows) of protein from the foetal circulation to the amniotic fluid. The orientation and relative proportions of the embryo are diagrammatic. E, Exocoelomic cavity; A, amnion; AC, amniotic cavity; VV, vitelline vessels; AV, allantoic vessels; YS, yolk sac splanchnopleur; U, uterus.

The composition and origin of human amniotic fluid components reflect this difference. Group-specific component and transferrin, unlike those in the mouse, have been shown to be of maternal origin<sup>11-14</sup>, and the relative proportions of different serum proteins in amniotic fluid throughout pregnancy resemble those in maternal serum11. Although the foetus makes some contribution13,16, the only proteins for which a foetal origin has been unequivocally demonstrated are hexosaminidase A and B, arylsulphatase A,  $\beta$  galactosidase and  $\alpha$  foetoprotein<sup>17-21</sup>. In man, the relative concentration of a foetoprotein in amniotic fluid and in foetal serum is 1:150 between 10 and 20 weeks11, whereas in the mouse it is approximately 1:10 at days 11-18. Clearly, the foetal contribution to amniotic fluid is more substantial in mice than man.

We thank the Ford Foundation for financial support.

#### Liposomes can mimic virus membranes

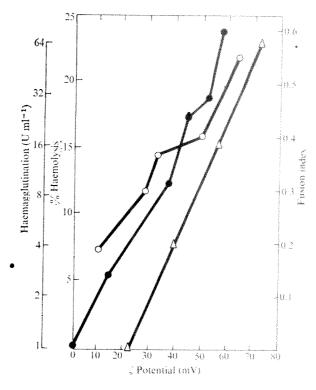

Considerable insight into mechanisms of membrane permeability and transport has been obtained from the study of simple lipid membranes. For the study of membrane-membrane interactions, however, such model systems have been used to a much lesser extent. If present ideas that biological membranes possess extended areas of lipid bilayer are correct, then it is probable that bilayer regions are involved in intermembrane phenomena such as adhesion and fusion, and it becomes reasonable to use simple lipid membranes to mimic such behaviour.

We set out to do this with respect to the membrane associated activities exhibited by many of the enveloped viruses. As the model virus, we used a modification of what has been described as a lipid dispersion, lipid vesicles, or liposomes, that is, single or multiple concentric shells of lipid bimolecular leaflets. The 'non-genetic' viral activities that are duplicated by the model virus membrane include attachment of the virus to the host cell. fusion of the viral membrane with the cytoplasmic membrane of the host cell, fusion of membranes of two or more host cells, and in the case of erythrocytes, haemolysis.

With respect to cell fusion, lysolecithin alone and in an oil emulsion has been used with success, although cell lysis is a problem<sup>1,2</sup>. Very recently, mixtures of phosphatidyl choline and either phosphatidyl serine (PS) or phosphatidyl glycerol in the form of liposome dispersions have been shown to be effective without adverse influence on cell viability<sup>3</sup>. In a related study, it was shown that lipid from phospholipid vesicles is incorporated into mycoplasma membrane, although the mechanism was not unequivocally elucidated4.

Lipid vesicles were prepared in the usual manner<sup>5</sup>. Lipids were dissolved in chloroform-methanol (4:1) which was subsequently removed under reduced pressure. The dry lipids were suspended at 2.5 mg ml<sup>-1</sup> in sucrose (0.3 M), EDTA  $(10^{-4} \text{ M})$  and tricine  $(2.0 \times 10^{-2} \text{ M})$  at pH 7.8 (stock lipid dispersion). Liposomes used in haemolysis experiments were then sonicated with a probe type apparatus for a few minutes at room temperature. Vesicles used in fusion experiments were sonicated further (40 min at 24° C) to yield a population with a high proportion of unilamellar vesicles<sup>6</sup>. Haemagglutination, haemolysis and cell fusion were assayed using standard virological methods. The zeta potential of liposomes was determined by microelectrophoresis7. The lecithin used in this study, diisostearoylphosphatidyl choline (L), was prepared by reaction of the appropriate anhydride with glycerophosphoryl choline in the presence of triethylisostearate\*. Lysophosphatidyl choline (LL) was prepared from this lecithin by hydrolysis with phospholipase A (ref. 9) and purified by ether precipitation. Stearylamine (SA, 99.5%) was purchased from Lachat Chemical

Figure 1 depicts the relationship between the zeta potential of liposomes containing up to 2% SA and the haemagglutination

Membrane activities are related to liposome surface O, Okada's fusion index for EATC<sup>16</sup> for liposomes containing 25% LL and various amounts of SA (0.2-3.0%). Haemolysis of sheep red cells by liposomes containing 20. LL and varying amounts of SA. △, Log<sub>10</sub> of the haemagglutination titre of liposomes (5 mg ml<sup>-1</sup>) containing only lecithin and SA. All functions are plotted against the zeta potential of the corresponding liposomes. The haemagglutination titre of lipo some dispersions was measured by the Salk pattern method13 using a 0.5 % (v/v) suspension of washed sheep red blood cells in 0.3 M sucrose buffered with 20 mM tricine (pH 7.6). For haemolysis experiments, equal volumes of a 10% suspension of the sheep cells in buffered sucrose and the stock liposome dispersion were mixed at 4° C and the cells were allowed to The temperature was then raised to 37° C. After agglutinate. 30 min, % haemolysis was determined by the method of Neurath and Sokol12. Ehrlich ascites tumour cells for fusion experiments (EATC) were grown intraperitoneally in adult Swiss mice of both The cells were then washed three times with Hank's balanced salt solution (BSS) to remove contaminating crythrocytes and suspended at a concentration of 10 % (v/v) in 0.3 M sucrose buffered to pH 7.8 with 20 mM tricine-NaOH. 0.25 ml of lipid dispersion was added to 1 ml of a 10% EATC suspension. The incubation procedure for fusion was the same as that used in the haemolysis experiments. Fusion was assayed using methods described by Okada<sup>16</sup>

(HA) titre of a dispersion containing 5 mg ml<sup>-1</sup> lipid. When plotted on a logarithmic unit scale, the relationship is linear up to 70 mV, above which value it would no longer be expected that the zeta potential would be an accurate measure of the surface potential. That the liposomes are the actual agglutinating agent rather than unincorporated SA is indicated by the following observations. First, when such dispersions are centrifuged at speeds sufficient to sediment liposomes but not SA micelles, 99% of the HA activity is found in the pellet. Second, the zeta potential of liposomes is proportional to the SA content and is stable for hours, indicating that there is little tendency for the SA to leave the liposomes.

Inclusion of LL into positively charged liposomes renders them active in the lysis of sheep erythrocytes. At constant surface charge density, the haemolysis rate increases with increasing LL content. Similarly, at constant LL values, the extent of haemolysis increases linearly with zeta potential. This is illustrated in Fig. 1. Neutral and negatively charged vesicles are devoid of haemolytic activity at the concentrations tested. We have compared the time course of liposome-induced haemolysis with that which has been reported for EDTAtreated Sendai virus and, aside from a scaling factor, the relationships are virtually identical. In addition, there is a linear relationship between the concentration of liposomes (HA titre) and the logarithm of percentage haemolysis, the same kind of relationship that obtains with EDTA-treated Sendai virus<sup>13</sup>.

Liposomes capable of haemolysis also promote fusion of actively metabolising cells. Two animal cell types, EATC and KB, exhibit extensive cell fusion following treatment of cultures with L-LL-SA liposomes. Micrographs of representative examples of polykaryons of such cells are shown in Fig. 2. In our experience polykaryons produced by liposomes and Sendai virus are indistinguishable. As is the case with the fusion-promoting viruses, suspended cells treated with liposomes agglutinate at 4° C and begin to fuse as the temperature is raised. The fusion index for EATC increases with both LL content and positive surface potential of the liposomes. The latter relationship is shown in Fig. 1, the data in which represent fusion indices determined shortly (30 min) after liposome treatment. Although, as is the case with virus-induced fusion, there is some loss of cell viability, it is rather minimal. For example, 30 h after a 15 min treatment with liposomes containing 20% LL and 5% SA, fusion indices were 45±5% for KB and rabbit kidney cells and 0.58 (Okada's index for cells in

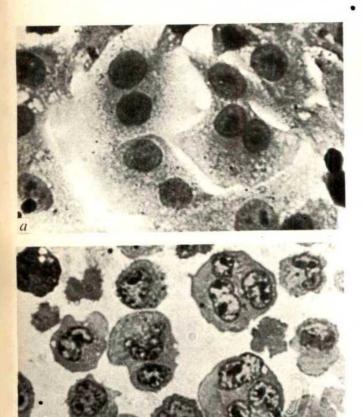

Fig. 2 Liposome-induced cell fusion. Polynuclear cells formed following treatment of a, KB cells monolayer and b, Ehrlich ascites tumour cells in suspension, with liposomes containing 20% LL, 5% SA and 75% L. 0.25 ml lipid dispersion was added to 1 ml of a 10% EATC suspension or to a KB monolayer in a 25 cm² culture flask containing 5 ml BSS. KB cells were grown in Eagle's minimal medium (EMM) and supplemented with 20% heat inactivated foetal calf serum in 25 cm² plastic flasks. The cultures were grown to confluence and maintained in EMM supplemented with 5% calf serum. For fusion experiments, the monolayers were washed with prewarmed BSS and treated with 0.25 ml of the liposome suspension at 37° C for 15 m. The cultures were then washed with BSS to remove excess liposomes and fresh maintenance medium added. For fusion assays, the cells were washed with BSS, treated with 0.02% EDTA in PBS for 1 min, fixed with 2% glutaraldehyde, stained with May-Greenwald Giemsa stain and polynuclear cells counted as described by Kohn<sup>14</sup>. EATC were treated as described in the legend to Fig. 1.

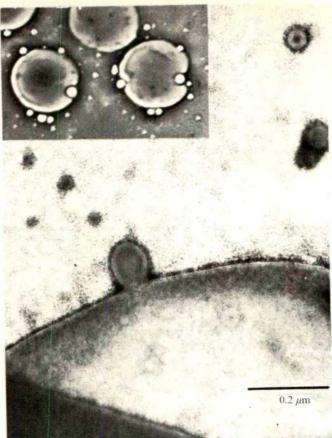

Fig. 3 Electron micrograph of a negatively stained preparation of human red cells treated with liposomes. A liposome is seen fusing with the erythrocyte membrane (Bar represents 0.1 μm). The inset is a phase micrograph of liposomes of the same composition adhering to the surface of red cells (×900). Freshly drawn human group O erythrocytes were washed five times with PBS and suspended at a concentration of 50% (v/v) in 0.3 M sucrose containing 0.1 M phosphate buffer (pH 7.3). The cells were then treated with unsonicated liposomes containing 20% LL, 5% SA and 75% L for 5 min at 37° C. A drop of the cell suspension was then lysed at the air-water interface and red cell ghosts floating on the surface were picked up on carbon strengthened parlodion grids. Without letting the preparation dry, the cells were fixed in osmium vapour for 5 min. The excess water was then removed from the grid surface with blotting paper and a drop of 2 potassium phosphotungstate (pH 6.5) was immediately placed on the grid. After 30 s the excess stain was removed with blotting paper and the preparation was allowed to air dry. The grids were then examined in a Hitachi 11-A electron microscope. For light microscopy, grids containing unstained liposome-treated ghosts were examined directly under the phase microscope.

suspension) for EATC. In all cases about 10% of the cells died (trypan blue exclusion) or detached from the substrate. This degree of cell loss accompanies each treatment; the extent of fusion, however, can be increased by multiple exposures of cells to the liposomes. Cell damage can be minimised by decreasing the liposome/cell ratio. In our experiments, each cell was treated with about 10s liposomes. This amount can be reduced by four orders of magnitude, and the fusion index is lowered by only 10%. At such low liposome levels, the decrease of cell viability in fusion experiments is reduced to practically nothing. These results are similar to those reported by Papahadjopoulos et al.<sup>3</sup> for what they found to be the most efficient lipid mixture, L and PS. We have not obtained appreciable fusion with PS liposomes in our conditions.

By electron microscopy, enveloped viruses have been observed fusing with cell membranes<sup>15–19</sup>. It has been suggested that infection occurs by the same mechanism and, further, that binucleate cells are formed by the simultaneous fusion of the virus membrane with the membranes of two cells<sup>17</sup>. The fusion of liposomes with cell membranes may also be seen by electron

microscopy. Figure 3 is an electron micrograph of an L-LL-AS liposome in an intermediate stage of fusion with a human erythrocyte. A variety of such electron micrographs of cell membranes taken shortly after treatment with L-LL-SA liposomes reveals various stages from simple adhesion to nearly complete incorporation. The inset is a phase micrograph of liposomes of the same composition adhering to the surface of

The advantages of using simple artificial means to produce hybrid cells for genetic and other experiments have been noted3. The use of liposomes circumvents the necessity of finding a virus competent to fuse the cells of interest. As all cell membranes are negatively charged, the receptor for an 'artificial virus' of the type described here is universal. Model viruses also offer the opportunity of introducing foreign molecules into intact cells or into their membranes by incorporating such molecules into the aqueous or membrane phase, respectively, of the liposome20.

The data presented here show that a lipid bilayer vesicle behaves like some virus membranes when a long chain cation and a lytic lipid are incorporated into it. It is possible therefore, that the basic requirements for viral membrane proteins that participate in infection activities, are to recognise specifically the host cell as, for example, would an antibody, and to disorder bilayer membranes in a manner similar to that of lyso compounds and detergents. We do not intend to imply either that viruses are positively charged or that lysolecithin is a necessary viral membrane component.

#### Incorporation of lipid vesicles by mammalian cells provides a potential method for modifying cell behaviour

PHOSPHOLIPID vesicles (liposomes1) have been used extensively as models for natural membranes1.2. Multilamellar vesicles are incorporated by mammalian cells both in vivo3,4 and in vitro5. Sonication of such vesicles creates small (250-500 Å diameter)

closed spherical vesicles composed of a single lipid bilayer enclosing an aqueous space2. Cultured mammalian cells will also incorporate these unilamellar vesicles without cytôtoxic effects6. We present here data on the uptake of unilamellar vesicles by cells in vitro and the use of these vesicles as carriers to introduce biologically-active molecules into specific regions of the cell.

Incorporation of unilamellar vesicles with negative or positive surface charge by mouse 3T3 and L929 cells and human erythrocyte ghosts is shown in Fig. 1. Each cell type incorporated substantial numbers of vesicles (1 nmol lipid =  $2 \times 10^{10}$ 

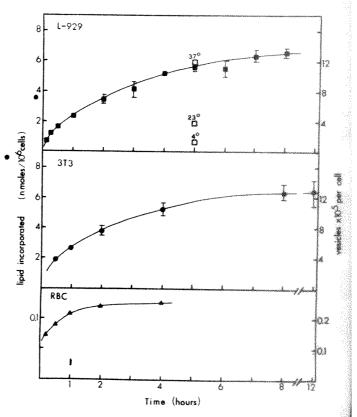

Fig. 1 Incorporation of unilamellar lipid vesicles by mouse 313 and L929 cells and human erythrocyte ghosts, at 37° C. Vesicles were prepared by dispersion and sonication of highly purified lipids in calcium and magnesium-free Hanks solution, pH 7.4, as before using 4 µmol of phospholipid in 2 ml. Preparations were centrifuged at 100,000g for 30 min before use to remove contaminating multilamellar vesicles. Lipids were synthesised and purified as before? Phosphatidylserine (PS) was from bovine brain and phosphatidylcholine (PC) from egg yolk. BALB/c mouse 3T3 cells and mouse L929 cells were cultured as before<sup>6.7</sup>. Human erythrocyte ghosts were prepared from fresh blood by the method of Jung et al.8 which yields 'resealed' ghosts with a restored permeability barrier to small solutes. 3T3 and L929 tell populations were incubated with vesicles as before. Erythrocyte ghost preparations were equilibrated in 50 mM NaCl, 2 mM histidine, 2 mM N-Tris (hydroxymethyl)-methyl-2-aminoethane sulfonic acid (TES) and 0.1 mM EDTA, pH 8.2, before incubation with vesicles. I lalex tion with vesicles. Unless stated otherwise, vesicle incorporation by cells was measured at 37° C by the uptake of 3H-dipalmitoylphosphatidylcholine (\*H-DPPC) (specific activity 4 Cimmol added in trace amounts during the formation of vescicles as described previously. L929 cell monolayers and erythrocyte ghosts in suspension were incubated with vesicles composed of PS, PC and cholesterol (1:9:8 molar ratio and trace amounts of <sup>3</sup>H-DPPC). 3T3 cell monolayers were incubated with vesicles containing stearylamine, PC and cholesterol (1:4:3 molar ratio and <sup>14</sup>C-cholesterol as a tracer). 3T3 and L929 cells were exposed to an input of 50 nmol of phospholipid per  $10^8$  cells (approximately  $1\times10^7$  vesicle per cell). Erythrocyte ghosts were treated to an input dose of 1.3 nmol of phospholipid per 10° cells. 3T3 and L929 cell monolayers were suspended by treatment with 0.2% trypsin and 0.2% EDTA in Hanks saline at intervals after incubation with vesicles and the amount of cell-associated radioactivity measured as before. ■, L929 cells incubated at 37° C; ☐, L929 cells incubated at 37° C, 23° C and 4° C as designated in the figure; ●, 3T3 cells at 37° C; ▲, erythrocyte ghosts at 37° C.

vesicles)7 but the kinetics were different in each case. For 3T3 and L929 cell cultures, the maximum incorporation of vesicles shown in Fig. 1 represents between 2 and 5% of the vesicle population, while ghosts incorporated up to 10% of the vesicle population. Dye-exclusion measurements revealed no significant change in the viability of vesicle-treated 3T3 and L929 cells compared with untreated cells and their growth rate remained comparable with that of controls during successive subcultivations for 3 months. Figure 2 shows that vesicle uptake by 3T3 cells was linear over a 10,000-fold concentration range. Vesicle incorporation by L929 cells and erythrocyte ghosts was also generally similar. Chemical analysis of the lipid content of L929 cells and erythrocyte ghosts after a 6 h incubation with phosphatidylserine (PS)/phosphatidylcholine (PC) cholesterol (1:9:8 molarratio) vesicles (conditions as in Fig. 1) revealed respectively a 20% and 15% increase in total phospholipid. Extraction of cell lipids in chloroform-methanol and thin-layer chromatography of the extracted lipids after incubation with PS/PC/cholesterol vesicles plus trace amounts of 3H-dipalmitoyl phosphatidylcholine (3H-DPPC) revealed that 70% of the incorporated 3H-DPPC label co-chromatographed with pure samples of PC, PS and phosphatidylethanolamine (PE). Tritium label was recovered from both plasma membrane and intracellular membrane fractions.

Uptake of unilamellar lipid vesicles by cultured cells was temperature-dependent (Fig. 1). Uptake of vesicles by cells was not significantly altered by inhibition of cellular energy metabolism by incubating cells for 30 min with sodium azide  $(2 \times 10^{-4})$ M) or sodium iodoacetate  $(2 \times 10^{-4} \text{ M})$  before addition of vesicles. Similarly, preincubation of cells with ouabain (10<sup>-3</sup> M) for 1 h had no effect on vesicle incorporation, and pretreatment with 10 µg ml<sup>-1</sup> polylysine (molecular weight 2,800) for 1 h to stimulate endocytosis9 also failed to alter the extent of vesicle uptake. Negatively charged (PS), neutral (PC) and positivelycharged vesicles (20% stearylamine in PC) were incorporated equally well by cells. Comparable incorporation was also found using vesicles composed of lipids that were 'fluid' (10% PS in PC) or 'solid' (10% PS in distearoylphosphatidylcholine) at 37° C. Incorporation of equimolar amounts of cholesterol into 'fluid' (PS/PC) or 'solid' (PS/DPPC) vesicles produced no substantial change in cellular uptake of vesicles. In spite of these general similarities, 'fluid' lipid vesicles can be incorporated into cells by a different pathway than 'solid' vesicles (see below).

Vesicle components could be incorporated into cells by several non-exclusive mechanisms. Exchange diffusion of lipid molecules (cholesterol) between vesicles and natural membranes

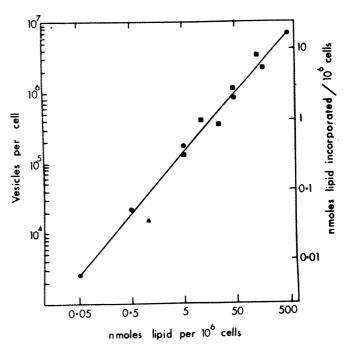

Fig. 2 Incorporation of unilamellar lipid vesicles by mouse 3T3 and L929 cells exposed to different concentrations of vesicles. 3T3 cells (●) were incubated for 4 h at 37° C with stearylamine, PC and cholesterol vesicles (1:4:3 molar ratio with ³H-DPPC as a tracer). Vesicle uptake was determined by measurement of cell-associated radioactivity as in Fig. 1. L929 cells (■) and erythrocyte ghosts (▲) were incubated for 4 h at 37° C with PS, PC and cholesterol vesicles (1:9:8 molar ratio with ³H-DPPC as a tracer).

has been documented<sup>10,11</sup>. Alternatively, vesicles can be incorporated intact by cells either by fusing with the plasma membrane or by endocytosis. Finally, the recovery of 'markers' from vesicles in association with cells might merely reflect binding of vesicles to the cell surface without incorporation *per se*. Incubation of L929 or 3T3 cells with PS/PC/cholesterol vesicles containing trace amounts of <sup>14</sup>C-cholesterol and <sup>3</sup>H-DPPC 'markers' revealed that the ratio of <sup>3</sup>H to <sup>14</sup>C counts recovered in association with cells after incubation with vesicles was similar (1:1.8) to the ratio in the original vesicle population (1:1.9), suggesting incorporation of intact vesicles. The parallel uptake of <sup>3</sup>H-DPPC and <sup>14</sup>C-cholesterol suggests tha

Plastic Petri dishes (60 mm) were seeded with  $3 \times 10^5$  3T3 cells and incubated at  $37^{\circ}$  C for 24 h. The culture medium was then replaced with medium containing unilamellar lipid vesicles, similar vesicles containing  ${}^3$ H-cyclic AMP or medium containing  ${}^3$ H-cyclic AMP plus  $10^{-3}$  M theophylline or dibutyryl cyclic AMP plus  $10^{-3}$  M theophylline, and the number of cells were counted at intervals. Control cultures were incubated in normal medium without vesicles or cyclic nucleotides. Vesicles containing cyclic AMP were prepared as described before. The results represent mean values from three separate experiments. Fluid vesicles were stearylamine, PC and cholesterol (molar ratio 1: 4: 3); solid vesicles were stearylamine, DPPC and cholesterol (1: 4: 4, molar ratio). Both fluid and solid vesicles contained trace amounts of

molecular exchange between cell membranes and vesicles is not the major mechanism for uptake of vesicle components since cholesterol would exchange at a faster rate10. The lack of effect of inhibitors of energy metabolism on vesicle uptake (see above) suggests that classical endocytosis is probably not involved, though incorporation of material with molecular weights lower than 2×105 by metabolically-independent endocytotic mechanisms has been described12.

We have also studied the cellular uptake of vesicles (stearylamine/PC/cholesterol; 1:4:3 molar ratio) containing 3H-cyclic adenosine 3': 5' monophosphate (3H-cyclic AMP) trapped within the internal aqueous space<sup>6</sup>. Incubation of 3T3 cells with such vesicles resulted in significant uptake of both <sup>14</sup>C-cholesterol and <sup>3</sup>H-cyclic AMP molecules from the vesicles (Table 1). Vesicle-incorporated cyclic AMP produced significantly greater inhibition of cell growth than equivalent concentrations of exogenous cyclic AMP or dibutyryl cyclic AMP plus theophylline (Table 1). Since the growth inhibition by exogenous nucleotides was similar to that reported for free nucleotides13, our results indicate that vesicles offer an efficient carrier vehicle for increasing the uptake of biologically important molecules into cells. The ratio of 3H to 14C counts recovered from vesicletreated cells was similar to that of the original vesicle population, supporting the earlier suggestion that intact vesicles are incorporated.

The alteration of cell growth by cyclic AMP-containing vesicles suggests that active cyclic AMP is released from vesicles into the cytoplasm. The simplest, but not the only possible interpretation for this presumed cytoplasmic distribution of cyclic AMP, is that some vesicles may fuse with the plasma membrane, introducing their contents directly into the cytoplasm. Using the same experimental protocol, 3H-cyclic AMP trapped within vesicles prepared from 'solid' lipids (stearylamine/DPPC/cholesterol) did not induce significant alteration in cell growth in spite of significant vesicle uptake (Table 1). This contrasting effect between 'fluid' and 'solid' vesicles could reflect differences in the 'leakiness' of the two types of vesicles for the trapped cyclic AMP. Alternatively, the vesicles may differ in their ability to fuse with the cell surface. 'Solid' lipid vesicles are unable to fuse cells7 and have a very limited capacity

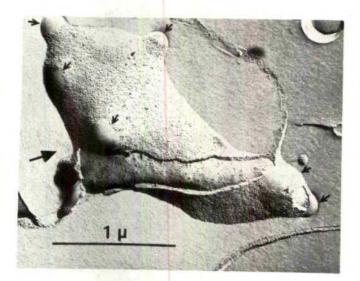

Fig. 3 Electron micrograph of freeze-fractured humanerythrocyte ghost after incubation with multilamellar lipid vesicles, showing areas (small arrows) devoid of intramembranous particles. Vesicles (PS/PC, 1:9 molar ratio) were dispersed by mechanical (vortex) agitation in 50 mM NaCl, pH 8.2. Incubation with ghosts was performed in the same buffer with 1.3 nmol phospholipid per 10<sup>6</sup> cells, for 30 min at 37° C. The cells were spun down at room temperature and resuspended in 30% (v/v) glycerol, frozen in Freon 22, fractured at -115° C in a Balzers BA360 apparatus and shadowed with platinum-carbon as before17. Large arrow indicates direction of shadowing.

to fuse with each other compared with 'fluid' vesicles14, 'Soli vesicles containing cyclic AMP might not, therefore, be able fuse with the plasma membrane and may be incorporate primarily by endocytosis, introducing their contents instead into the lysosomal apparatus. This would reduce the likelihoo of cyclic AMP reaching the cytoplasm in an active form, sin lysosomes contain several phosphodiesterases15

The incorporation of lipid molecules from 'fluid' vesicles in the plasma membrane, presumably by fusion, is further su gested by the recovery of radiolabelled lipid in the plasm membrane fraction of fractionated cells (see above) and also I changes in the lectin agglutinability, and membrane transpo properties of vesicle-treated cells (our work in preparation Figure 3 shows a freeze-fractured erythrocyte ghost aft incubation with multilamellar PS/PC vesicles. The 'ba patches' on the ghost were found in 5% of the treated cells, b were not found on several hundred fields of untreated control The dimensions and surface topography of the 'patches' a very similar to vesicles and it is tempting to interpret that the areas represent sites where vesicles have fused with the plasm membrane. Also, the density of intramembranous particles of vesicle-treated cells not showing 'patches' was significant lower than in untreated cells (our work in preparation), which suggests that the cell surface area had increased.

Our results indicate that mammalian cells can incorpora large numbers of lipid vesicles without cytotoxic effects. Fusic of vesicles with the plasma membrane may represent an impo tant pathway for vesicle incorporation, though endocytosi surface adsorption and molecular exchange between vesicle and cell membranes may also be occurring simultaneously Although the precise contribution of different pathways in the incorporation of vesicles into cells remains to be elucidated, th present results, together with other recent studies, indicate the lipid vesicles offer a potentially useful tool for modifying ce behaviour by introducing new material into the plasma men brane (ref. 16 and our work in preparation), and by the deliver of biologically active molecules and drugs into the cell3-Independent data on vesicle uptake by mammalian cells as given by Pagano et al.18 in the next communication.

# Interaction of phospholipid vesicles with cultured mammalian cells

To delineate some of the relationships between membrane composition and the functional states of mammalian cells, we are exploring the possibility of producing controlled modifications in the plasma membrane of cultured cells, using artificially generated lipid vesicles1-3. Although other groups have reported the use of lipid dispersions for producing cellular modifications4-10, the underlying molecular mechanisms by which these effects are produced have not been determined. We present here preliminary findings on the mechanism of interaction of chemically and physically well-defined phospholipid vesicles with cultured mammalian cells.

Typical data obtained when Chinese hamster V79 cells were incubated with vesicles produced from radiolabelled egg yolk lecithin are given in Fig. 1. Unilamellar (F-II) vesicles were more efficient in the transfer of exogenous phospolipid to the cells than multilameller (F-I) vesicles. In both cases a considerable amount of phospholipid became associated with the cells in a relatively short time. The amount of lipid taken up depended on the physical state of the lipids comprising the vesicles, being substantially greater below the gel-liquid crystalline phase transition temperature. Between 20% and 30% of the labelled phospholipid taken up by vesicle-treated cells appeared in their plasma membranes. This lipid was not degraded, but remained as lecithin. The remaining radioactivity was distributed into intracellular fractions in which considerable degradation was observed. No effect on cell viability could be detected for short periods of incubation (up to 6 h), and normal cell growth resumed when the vesicle suspension was replaced by fresh medium. Prolonged incubation of sparse cultures (~103 cells cm-2), however, resulted in considerable cell death as determined by dye exclusion tests. This deleterious effect of lipid vesicle treatment agrees with our observation that sparse cultures take up about an order of magnitude more phospholipid than those approaching confluency.

Figure 2a shows a transmission electron micrograph obtained from a thin section through a preparation of V79 cells incubated with a suspension of F-I vesicles. A large vesicle, about 7,000 Å in diameter, with the characteristic multilamellar appearance of this vesicle fraction, is seen in direct contact with the plasma membrane of the cell. Figure 2b shows a preparation of unilamellar vesicles, about 500 Å in diameter, incubated with V79 cells pretreated with cationised ferritin<sup>12</sup> (0.5 mg ml<sup>-1</sup> for 5 min at 25° C). There are numerous vesicles, both attached to the surface membrane and apparently fused with the cell. Although there were no essential differences in the amount of phospholipid taken up in the presence or absence of cationised ferritin, the fate of the applied unilamellar vesicle suspension could not be traced by electron microscopy without this marker.

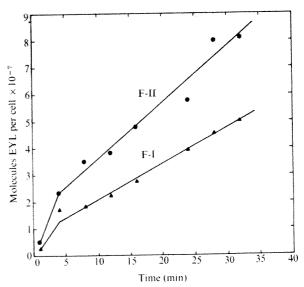

Fig. 1 Uptake data obtained for V79 cells incubated with Fig. 1 Uptake data obtained for V79 cells incubated with egg yolk lecithin (EYL) vesicles at 25° C. Vesicles were prepared by ultrasonic irradiation of radiolabelled EYL in Gey's balanced salt solution¹¹¹. The radiolabelled lipid was prepared by adding a trace amount of ∼5 Ci mmol⁻¹ ³H-distearoyl lecithin to EYL to give a product with a final specific activity of 1 mCi mmol⁻¹ EYL. The lipid dispersion was fractionated by get permeation chromatography³ into was fractionated by gel permeation chromatography<sup>3</sup> into multilamellar (F-I) and unilamellar (F-II) fractions, and diluted in each case to a concentration of 0.09 mM lipid phosphorus. In a typical experiment, a culture plate containing  $\sim 10^7$  cells was washed in Gey's, followed by the addition of the labelled vesicle suspension. After incubation the plate was washed thoroughly, the cells briefly trypsinised, and the resulting cell suspension repeatedly centrifuged and resuspended in Gey's. The radioactivity in the final pellet was determined, and the total number of phospholipid molecules taken up per cell was calculated. Error is ±5%.

The uptake of phospholipid from either unilamellar or multilamellar vesicles by cells was insensitive to inhibitors of energy metabolism (30 mM NaN3; 0.1 mM dinitrophenol). Cells pretreated with 2% glutaraldehyde (2 h at 4° C) before uptake showed about a 25% reduction in the amount of phospholipid taken up after 1 h of incubation. These observations strongly suggest that the incorporation of exogenous phospholipid from vesicles by the cultured cell system examined here is not energy dependent. Accordingly, in considering the possible mechanisms of uptake, we rule out active processes such as endocytosis, and consider only the following: (i) vesicle-cell fusion; (ii) phospholipid exchange, similar to that described for in vitro 13,14 systems in which phospholipid molecules from the vesicle suspension and plasma membrane of the cell are interchanged and (iii) adsorption, in which the exogenous

No leakage of the trapped marker could be detected during this experiment. † Protocol as in Fig. 1; 1 h incubation.

phospholipid from the applied vesicles is adsorbed to the cell surface, resulting in a net transfer of lipid to the cell.

If fusion is involved in the interaction of phospholipid vesicles with cultured cells, then the aqueous contents of such vesicles should be released into the cytoplasm of vesicle-treated cells after each fusion event. To test this possibility, vesicles comprised of 14C-dioleyl lecithin and containing 3H-inulin as a marker for the internal aqueous volume were used in an uptake experiment (Table 1). If all the phospholipid enters the cell by fusion, the ratio of phospholipid to inulin radioactivity found associated with vesicle-treated cells should be that of the applied vesicle suspension. Table 1 shows the amounts of <sup>14</sup>C-dioleyl lecithin and 3H-inulin found associated with cells treated with either multilamellar or unilamellar vesicles together with the observed and expected ratios of c.p.m. of "C to tritium. The observed ratios were calculated from the 14C-lecithin and 3H-inulin taken up by the cells for each treatment, whereas the expected values were derived directly from the measured ratios of the applied vesicle fractions. In each case the amount of the trapped marker, 3H-inulin, which became cell-associated was not proportional to the

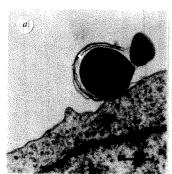

Fig. 2 Transmission electron micrographs of V79 cells incubated for 1 h at 37°C (a) with multilamellar vesicles generated from EYL, and (b) with unilamellar vesicles generated from dioleyl lecithin. In (b), cells were pretreated with cationised ferritin (see text). Cells were pre-fixed in 0.1 M cacodylate buffer (pH 7.2) containing 2% glutaraldehyde, fixed in 1%  $OsO_4$ , stained in uranyl acetate and embedded in Epon. Thin sections were stained with lead citrate. The bar represents 0.5  $\mu$ m.

amount of phospholipid taken up. For example, for multilamellar vesicles at 37° C, the observed ratio of phospholipid c.p.m. to inulin c.p.m. was 3.4, compared with an expected value of 0.41. If the trapped marker can become associated with the cell only as the result of fusion, we calculate that at 2° C, only small amounts of the observed phospholipid uptake (<2% for multilamellar and  $\sim10\%$  for unilamellar vesicles) can be accounted for by fusion, whereas at 37°C, more significant fractions of the lipid uptake ( $\sim 10\%$  for multilamellar and  $\sim 50\%$  for unilamellar vesicles) could enter the cells by such a mechanism. The remaining lipid would have to be taken up by some other pathway such as phospholipid exchange or adsorption. Experiments are in progress to test these possibilities. Similar studies of cells pretreated with glutaraldehyde demonstrated that the association of the trapped marker with vesicle-treated cells was not significantly inhibited, thus confirming the supposition that vesicle uptake is not an active process.

To demonstrate unequivocally that a fusion process is involved in the overall mechanism of uptake of unilamellar vesicles by cultured cells, we require in addition to the uptake of phospholipid and trapped marker, that the following criteria be met. First, the trapped marker must be truly soluble in the internal aqueous space of the vesicle.

The use of lipid vesicles bearing a net charge to entrain soluble markers of opposite charge raises the question of whether such markers are bound or associated with the wall of the lipid vesicle. If such an interaction exists, the bound marker might enter the cell by some internalisation mechanism and not by fusion. Second, the marker once associated with the cell must be demonstrated to be free within the cytoplasm of the cell and not compactmentalised either in the lysosomal apparatus or in some other membrane-bound vesicular body. Although we believe that the first condition has been fulfilled in our studies, we have no sufficient proof that the second criterion has been met. Thus we can only suggest vesicle-cell fusion as an explanation for our observations. Nevertheless, these studies should provide a useful basis for achieving modification of the surface properties of mammalian cells.

# Yeast mitochondrial RNA does not contain poly(A)

POLY(A) is a universal constituent of eukaryotic messenger RNAs with the exception of histone mRNA1. Recently Penman and Attardi<sup>3</sup> have demonstrated that poly(A) was also present in mitochondrial RNA from animal cells. This finding was o interest to us for two reasons. First, it suggested a simple means of isolating mitochondrial mRNAs and, second, I suggested that the similarity between prokaryotes and mitochondria might not be as close as previously suggested. We therefore looked for poly(A)-containing RNA (poly(A)-RNA in the simple eukaryote Saccharomyces carlsbergensis.

Intact yeast mitochondria are difficult to isolate quickly from whole cells. Since rapid isolation should be a prerequisite for the characterisation of RNA pulse labelled for short periods, we preferred to pulse label isolated protoplasts. Using this system McLaughlin *et al.*<sup>5</sup> have detected considerable amounts of poly(A)-RNA in yeast polysomal RNA. Details of our protoplast preparation are described elsewhere (G.S.P.G., and R. O. Poyton, unpublished).

Yeast protoplasts were pulse labelled for 30 min with  $^3$ H-adenine, then quickly cooled and lysed by osmotic shock. After the removal of nuclei and cell debris, mitochondrial and post-mitochondrial fractions were prepared and RNA extracted from these by the hot-phenol-chloroform method of Penman? After extraction the RNA was precipitated with two volumes of ethanol and stored at  $-20^{\circ}$  C overnight. The recoveries of both  $^3$ H-labelled RNA and added  $^3$ P-labelled poly(A), as determined by acid-insoluble radioactivity, were always greater than  $90^{\circ}$ 0.

To test whether poly(A)-RNA was present, aliquots fapproximately 20,000 c.p.m.) of the mitochondrial and cell-sap RNA were fractionated on oligo(dT) cellulose columns as described by Faust et al.8. The results of such a fractionation are given in Fig. 1. It can be seen that, whereas 30% of the cell-sap RNA is retained by the column and elutes at low salt concentrations (Fig. 1b), less than 0.6% of such material is present in the mitochondrial RNA (Fig. 1a). The binding of the mitochondrial RNA was unaffected by previous denaturation (2 min, 100° C in 0.5 mM EDTA, pH 7.5). As an internal control 32P-labelled poly(A) was added and indeed eluted exclusively at low salt concentrations. To exclude the possibility that the cell-sap poly(A)-RNA was bound by a nonspecific process, competing poly(U) was added to a second aliquot of this RNA plus internal 32P-labelled poly(A). As expected, both the 3H and 32P radioactivity was no longer retained by the oligo(dT) cellulose (Fig. 1c), demonstrating that the cellsap RNA was indeed bound by its poly(A) moiety. Since the recovery from our oligo(dT) cellulose columns was 95-110%, we conclude that mitochondrial RNA pulse-labelled for 30 min. does not contain a poly(A) sequence of sufficient length to bind it to the oligo(dT) cellulose column. Identical results were obtained using chromatography on poly(U) Sepharose

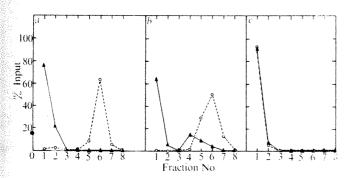

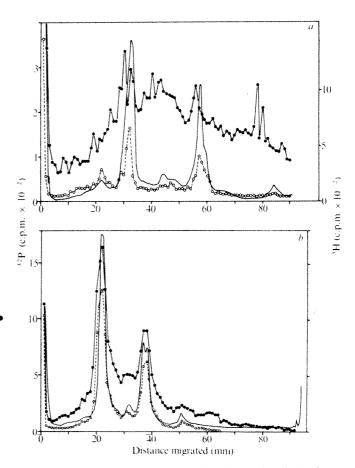

Fig. 1 Fractionation of pulse-labelled RNA on oligo(dT) cellulose columns. 4 g of yeast (S. carlsbergensis NCYC 74) protoplasts were labelled for 30 min at 28° C with <sup>3</sup>H-adenine (17 mCi l<sup>-1</sup>) in 200 ml growth medium, supplemented with 1.0 M sorbitol; cell-sap and mitochondrial RNA was prepared as described in the text; aliquots (20,000 c.p.m.) in 0.5 M KCl, 0.01 M Tris, pH 7.5, were mixed with <sup>32</sup>-P-labelled poly(A) (10,000 c.p.m.), prepared as described<sup>14</sup>, and applied to the oligo(dT) cellulose column. The flow-through material was passed again over the column. Fraction 1: final flow-through; fraction 2, elution with 0.5 M KCl, 0.01 M Tris; fraction 3, 0.25 M KCl, 0.01 M Tris; fraction 4, 0.1 M KCl, 0.01 M Tris; fraction 7, 95% formamide, 0.01 M Tris; fraction 8, 0.1 M NaOH. The fractions were then precipitated with 5% trichloroacetic acid after the addition of 100 μg bovine serum albumin. The precipitates were collected on Whatman glass fibre filters (GF-81) and counted. Fig. 2 Polyacrylamide gel analysis of pulse-labelled mitochondrial RNA from yeast. Electrophoresis conditions: 2.4% acrylamide gels using the buffer system of Peacock and Dingman<sup>15</sup>. After scanning at 260 nm (——), gels were frozen at -70° C, sliced, extracted and counted<sup>16</sup>. C, <sup>3</sup>H-adenine longlabelled mitochondrial RNA added as internal marker during electrophoresis; •, <sup>32</sup>P pulse profile. a, 4 min pulse; b, 15 min pulse.

To minimise the chance that poly(A)-RNA was missed in our experiments because of degradation during the isolation of the mitochondria, the cell-sap fraction was maintained in ice for the same length of time used for the mitochondrial purification (2 h). The finding of 30% of the cell-sap RNA as poly(A)-RNA renders this possibility unlikely.

We considered it possible that the in vivo turnover rate of poly(A)-mitochondrial RNA was so rapid that very little could be detected in a 30-min pulse in contrast to the cell-sap system. We therefore prepared mitochondrial RNA pulse-labelled for 4, 15 and 30 min, respectively. Polyacrylamide gel electrophoresis of two of these preparations is shown in Fig. 2. The 4 min pulse-labelled preparation clearly contains much heterogeneous RNA, indicating that processing and maturation of at least rRNA, has not occurred. This is clearly evident in the 15-min pulse-labelled material. The presence of intact endogenous rRNAs in these preparations, however, excludes trivial explanations for the heterogeneous RNA such as degradation. The 4 min and 30 min pulse preparations were also applied to the oligo(dT) cellulose column (Table 1). Again less than 0.5% of the 32P-labelled RNA was retained by the column in contrast to the complete retention of the internal 3H-labelled poly(A) control. Total RNA from protoplasts pulse-labelled for 5 min with 3H-adenine contained 20% poly(A)-RNA. Moreover, we were able to show considerable amounts of poly(A)-RNA in the mitochondrial RNA from chick fibroblasts (Table 1). Finally, we have analysed RNA synthesised by isolated yeast mitochondria in vitro for poly(A) content. Again less than 0.4% poly(A)-RNA could be detected.

As explanation of these results, two possibilities remain: either there is no poly(A)-mitochondrial RNA in yeast or the

Table 1 % Poly(A)-RNA in pulse-labelled mitochondrial RNA

Labelling condition	Organism	Radio- active pre- cursor	Pulse time (min)	Input applied to oligo(dT) cellulose (c.p.m.)	RNA re- tained
In vivo	Yeast	32 <b>P-P</b> i	4	10,500	0.5
In vivo	Yeast	32P-P <sub>1</sub>	30	42,000	0.5
In vivo	Yeast	<sup>3</sup> H-adenine	30	4,840	0.6
In vitro	Yeast	<sup>3</sup> H-UTP	20	5,100	0.4
In vivo	Chick	<sup>3</sup> H-uridine	15	16,100	34.4

Yeast protoplasts (5–15 g, 20 g  $l^{-1}$ ) were pulse-labelled with either <sup>32</sup>P-orthophosphate (25–40 mCi  $l^{-1}$ ) or <sup>3</sup>H-adenine (4 mCi  $l^{-1}$ ) and mitochondrial RNA isolated as described in Fig. 1. To measure in vitro RNA synthesis, isolated mitochondria were incubated as described<sup>11</sup>, except that the medium was supplemented with 50 µM <sup>3</sup>H-UTP (specific activity 10<sup>6</sup> c.p.m. mmol<sup>-1</sup>). Chick fibroblasts were grown and pulse-labelled with <sup>3</sup>H-uridine as described<sup>12</sup> and mitochondria were purified as described by Borst et al.13. RNA was prepared and oligo(dT) cellulose chromatography performed as described in Fig. 1. The % retained is defined as the counts eluting in fractions 4-8.

poly(A) region is so short that it cannot be retained by the oligo(dT) cellulose and poly(U) Sepharose columns. Preliminary experiments showed that while polyacrylamide gel electrophoresis was capable of resolving a 50 nucleotide poly(A) segment<sup>5</sup> derived from cell-sap RNA by ribonuclease digestion9, no such component was present in mitochondrial RNA. Under these conditions, however, a poly(A) tract of less than 30 nucleotides would not have been detectable above the high background of completely digested RNA peaking ahead of the bromophenol blue marker. Since Jacobson et al.9 showed that a poly(A) segment of 25 was sufficient to bind Dictyostelium nuclear RNA to poly(U) Sepharose, we presume that if mitochondrial RNA contains a poly(A) segment, it must be considerably shorter than this. Such a poly(A) region differs so much from its homologue in the animal cell, that its possible existence becomes somewhat a semantic problem.

To us the most likely interpretation of our data is that mitochondria from yeast contain no poly(A)-RNA in contrast to animal mitochondria and in common with the RNA of prokaryotes and histone mRNA. Such a result is consistent with a prokaryotic origin for mitochondria and tempts us to suggest that poly(A)-mRNA in animal mitochondria is the result of adaption of a 'prokaryotic' genetic system to the demands of life in the higher eukaryote which occurred parallel to the loss of genetic information in the animal mitochondrial DNA (the potential coding capacity of yeast mitochondrial DNA is two to five times that of animals).

Finally, our results are in conflict with those of Cooper and Avers10, who reported poly(A)-mitochondrial RNA in yeast mitochondria. We attribute their results to contamination of the mitochondrial preparations with intact protoplasts.

We thank Mrs N. van Harten-Loosbroek and Mrs M. A. L. P. Ummels-Kremer for technical assistance. We also thank Dr C. H. Faust for the gift of oligo(dT) cellulose, Mr P. Capel for poly(U) Sepharose, Mr C. F. van Kreijl for <sup>3</sup>H-labelled poly(A) and RNA polymerase, Drs J. M. Coffin and G. Sheep for pulse-labelled chick fibroblasts, and Professor P. Borst for discussion. This work was supported (in part) by a grant to P. Borst from the Netherlands Foundation for Chemical Research (S.O.N.) with financial aid from the Netherlands Organisation for the Advancement of Pure Research (Z.W.O.).

### Large plasmid in Agrobacterium tumefaciens essential for crown gall-inducing ability

THE gram-negative bacterium Agrobacterium tumefaciens induces crown gall tumours in many, mostly dicotyledonous. plants. Zaenen et al.1 demonstrated the presence of one or more large plasmids in a number of crown gall-inducing Agrobacterium strains belonging to seven different Agrobacterium groups. They were not able to find such plasmids in eight non-pathogenic Agrobacterium strains belonging to four of the same groups<sup>2,3</sup>. They therefore formulated the hypothesis that the genetic information for the tumour-inducing principles in crown gall-inducing Agrobacterium strains is carried by one or several large plasmids.

Here we determine whether the large plasmids present in crown gall-inducing Agrobacteria are essential to the tumourinducing capacity of such strains. We show that, in a nontumorigenic derivative of a crown gall-inducing strain, the stable conversion to non-tumorigenicity is correlated with a concomitant loss of the large plasmid present in the parental strain. Second, we show for one tumour-inducing Agrobacterium strain that curing this strain of its plasmid in all cases resulted in the stable conversion of the cured strains to nontumorigenicity, the correlation between the loss of the plasmid and the loss of the tumour-inducing plasmid (TIP) being 100%

The crown gall-inducing Agrobacterium tumefaciens strain IIB and two of its derivatives, the tumorigenic strain IIBV7 and the non-tumorigenic strain IIBNV6, both isolated from strain IIB as single colonies, were compared (Braun, A. C., unpublished). Using ultracentrifugation on neutral sucrose gradients and caesium chloride-ethidium bromide equilibrium density centrifugation in the conditions described by Zaenen et al.1, we demonstrated the presence of a large plasmid in A. tumefaciens strains IIB and IIBV7. Fractions containing the plasmid peaks were examined under the electron microscope and large double-stranded DNA supercoiled molecules were photographed. Only the non-tumorigenic strain IIBNV6 did not contain a large plasmid when examined repeatedly.

Hamilton et al.5 reported that the crown gall-inducing strain C58 can very reproducibly be converted to a non-tumorigenic

strain by simple growth at 37° C. The resulting non-tumourinducing bacteria do not revert to tumorigenicity. We found that derivatives of A. tumefaciens strain B6 could neither be cured of their plasmid nor converted to non-tumorigenicity by growth at 37° C. For further study we therefore decided to concentrate on strain C58. By neutral sucrose gradient and caesium chloride-ethidium bromide centrifugation and subsequent electron microscopy, strain C58 was shown to harbour a large plasmid. Length contour measurements were carried out on open circular molecules. Analysis of the results showed an unimodal distribution, the mean contour length being  $61.8\,\pm\,1.1~\mu m$  (s.d.).

To obtain independently-isolated non-tumorigenic derivatives and to check the reproducibility of the conversion to non-tumorigenicity, strain C58 was streaked out for single colonies on a YEB agar plate1 and incubated for 5 d at 37° C. Six of the resulting colonies were separately collected, diluted and plated for single colonies on six different YEB agar plates at 28° C. Twenty-five colonies from each plate were tested for tumour induction on wounded seeds of Pisum sativum<sup>6</sup>. All 150 colonies tested proved to be non-tumorigenic. A total of 12 non-tumorigenic colonies (two from each plate) were cultured at 28° C and their DNA analysed on neutral sucrose gradients1. These non-tumorigenic bacteria were found to have lost the large plasmid present in the parental strain C58.

These results provide strong support for the hypothesis that the genetic information for the tumour-inducing principle in crown gall-inducing Agrobacterium strains is carried by one or more plasmids. The loss of tumour-inducing ability and loss of the plasmid, however, may be two unrelated events both brought about by growth at 37° C. If this were the case one would expect that in conditions where neither the curing of the plasmid nor the conversion to non-tumorigenicity would have occurred for all the population, one would find some bacteria for which only one of these events would have taken place. In order to realise such conditions we studied the kinetics of appearance of non-tumorigenic and of plasmid free bacteria in a strain C58 culture grown at 37° C.

An exponential culture of strain C58 grown in YEB medium at 28° C was diluted in fresh YEB medium to about 104 cells ml-1 and incubated at 37° C. When a titre of 109 cells ml-1 was reached, the culture was diluted to a titre of 104 cells ml-1 into fresh medium and further incubated at 37° C. This procedure was repeated several times. At different intervals samples were taken, the bacteria were diluted and plated for single colonies on YEB plates at 28° C. From each sample, several single colonies were tested on pea seedlings for tumour

Several tumourigenic and non-tumourigenic colonies derived from different samples were tested for the presence of a large plasmid. To be able to handle more colonies when searching for the presence of plasmids in Agrobacteria we modified the neutral sucrose gradient technique of Zaenen et al.1 by adding I ug ml-1 ethidium bromide (final concentration) to our sucrose gradients. Plasmid bands can be seen when the nitrocellulose centrifuge tubes are illuminated with long wave ultraviolet light. This eliminates the time consuming radioactive labelling, fractionating and liquid scintillation counting procedures.

All bacterial colonies that could induce crown gall tumours also harboured the large plasmid (Table 1), whereas all bacteria which had lost the ability to induce tumours had also lost the

plasmid. In all experiments special care was taken to make certain that we were not dealing with contaminants. This could easily be achieved by the use of a set of virulent Agrobacterium phages towards which strain C58 shows a characteristic sensitivity pattern.

As in all our experiments the correlation between loss of tumour-inducing capacity and loss of a large plasmid was found to be a 100%, we conclude that the presence of this plasmid is essential to the tumour-inducing ability of these strains. The most likely explanation for this would be that the plasmid in itself carries the genetic information for the tumour-inducing principle.

Such a conclusion, however, can only be reached if one can demonstrate induction of crown gall tumours with purified plasmid DNA. Our observations point to the possibility that bacterial plasmids could be oncogenic. Further work will be required to decide whether the role of this plasmid in tumour induction is directly due to the fact that it carries the genes of the tumour-inducing principle or merely because it somehow promotes the transfer of the TIP from the bacterium to the plant cell.

We thank Dr M. P. Gordon for the gift of strain C58, Mr J. P. Hernalsteens for the tests with virulent phages and Dr A. C. Braun for the A. tumefaciens strain IIB. We also thank Dr H. Teuchy for the electron microscope pictures and length measurements and Dr M. Van Montagu for helpful advice.

# Multiple divergent copies of endogenous C-type virogenes in mammalian cells

It is characteristic of endogenous C-type viruses that all individual animals of a species (as well as all tissues of each animal)

contain, in the chromosomal DNA, nucleic acid sequences that can code for the production of complete C-type viral particles. It is postulated that these sequences (C-type virogenes) are transmitted from parent to progeny with the other cellular genes1. Nucleic acid hybridisation, using either single-stranded or double-stranded 3H-DNA transcripts or labelled 70S RNA as viral probes, has revealed C-type viral nucleic acid sequences in DNA from uninfected tissues of avian<sup>2-5</sup>, murine<sup>6,7</sup>, porcine<sup>8</sup>, feline<sup>9-12</sup> and Old World monkey species<sup>13</sup>.

We have now examined the reiteration frequency of mouse, rat, pig, cat and baboon viral nucleic acid sequences in tissues and cell cultures of the species of origin of these viruses and in exogenously infected cells of heterologous species. While DNA from each species contains multiple copies of endogenous virogene sequences per haploid cellular genome (5-15), cell lines of heterologous species infected with and producing high titres of these C-type viruses contain fewer copies (one or two per haploid genome). The thermal stability of DNA:DNA hybrids demonstrates that the endogenous virogenes are composed of families of genes with related but not identical nucleic acid sequences.

We examined a xenotropic (S-tropic) virus isolated from a murine BALB/3T3 cell line14; the RD114/CCC group of endogenous cat viruses<sup>15,18</sup>; a C-type virus isolated from normal baboon tissue17; a porcine C-type virus spontaneously released by the pig kidney cell line, PK(15)8; and a rat C-type virus produced by a rat thymus cell line18.

The reassociation kinetics shown in Fig. 1 can be used to estimate relative gene frequencies by determination of the half  $C_0t$  values (the midpoint of the renaturation curve)<sup>19</sup>. Figure 1a shows that the half  $C_0t$  value for the hybridisation of the murine C-type viral <sup>3</sup>H-DNA probe to normal BALB/c strain mouse liver or to BALB/3T3 cell line DNA is  $1.1 \times 10^2$ – $1.2 \times 10^2$  $mol \times sl^{-1}$ ; whereas the half  $C_0t$  value for hybridisation with the DNA of either a canine or rabbit cell line infected with this virus is 1.5 imes 103. The half  $C_0 t$  value for the self-annealing of unique sequence rabbit and dog (Fig. 1), as well as mouse, cat, baboon and human cellular DNA has varied between  $1 \times 10^3$ and  $2 \times 10^3$  mol  $\times$  s  $1^{-1}$  (ref. 13). There is, therefore, only one or at most two copies of mouse C-type virus in the heterologous infected dog or rabbit cell lines, and there are approximately ten times this number of copies in the mouse cell line or in normal mouse tissue.

Sequences homologous to probes prepared from the endogenous baboon virus can be found in the DNA of various tissues of normal baboons<sup>13</sup>; as shown in Fig. 1b, the half  $C_0t$ value for this hybridisation is  $1.0 \times 10^2$ – $1.4 \times 10^2$ . In contrast, a cloned cell line infected with the baboon virus contains only one copy per haploid cell DNA (half  $C_0t$  value is  $1.0 \times 10^3$ ).

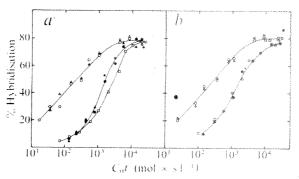

Fig. 1 Hybridisation of murine and baboon C-type viral H-DNA probes to DNA extracted from normal murine and baboon tissues and cell lines, and from cells from heterologous species infected with these viruses. The 3H-thymidine-labelled DNA probes were synthesised from detergent-disrupted C-type virus in the presence of actinomycin D<sup>27</sup>. The specific activity of the <sup>8</sup>H-DNA was 1.5 × 10<sup>7</sup> c.p.m. µg<sup>-1</sup>. The <sup>8</sup>H-DNA probes contained 50-75% of their respective 70S viral RNA sequences at a <sup>8</sup>H-DNA. <sup>28</sup>P-viral RNA molar ratio of 1.513, indicating that they contained most of the sequences present in viral RNA and that these sequences were in proportions similar to their content in 70S RNA. Cellular DNA was extracted from tissues and cell lines18. All DNAs were treated sonically to yield a mean size of 6-88 (the size of the <sup>3</sup>H-DNA probes) as determined by centrifugation on alkaline sucrose gradients<sup>13</sup>. DNA:DNA hybridisations were incubated at 65° C in reaction mixtures containing 0.01 M Tris, pH 7.4, 0.75 M NaCl, 2  $\times$  10<sup>-3</sup> M EDTA, 0.05% Sodium dodecyl sulphate, 10,000–20,000 c.p.m. ml<sup>-1</sup> of <sup>3</sup>H-DNA and 1–3 mg of cellular DNA per ml. Hybridisations were started by heating the mixtures to 98° C for 10 min, cooling on ice to 4° C, and incubating at 65° C. At various times (from 15 min to 96 h) 0.05 ml portions were removed and frozen at -80° C until digested with the single-strand-specific nuclease, S1, as described13. Cal values  $(C_0)$  is the concentration of cellular DNA in moles of nucleotide per litre, and t is the time in seconds) were calculated as suggested by Britten and Kohne<sup>28</sup> as A<sub>260</sub> per ml per 2 × h, and corrected to a monovalent cation concentration of 0.18 M<sup>28</sup>, a, Annealing of <sup>3</sup>H-DNA probe prepared from the xenotropic (S-tropic) BALB/c murine C-type virus<sup>14</sup> grown in canine thymus cells (FCf2Th) to DNA extracted from the BALB/3T3 cell line ( normal BALB/c liver (A), the canine thymus cell line (FCf2Th) infected with the S-tropic virus (♠); and a rabbit corneal cell line (SIRC)<sup>14</sup> infected with this virus (♠). Various concentrations of unique sequence rabbit cell line (SIRC) DNA (the highly reiterated DNA sequences that anneal by a  $C_0$ / of 50 were removed by fractionation on hydroxylapatite) and 4  $\times$  10 acid precipitable c.p.m. of 3H-thymidine-labelled unique sequence SIRC DNA (0.5 µg) were annealed (☐) as described above. b. Annealing of <sup>3</sup>H-DNA probe prepared from the baboon virus<sup>12</sup> grown in the human rhabdomyosarcoma (A204) cell line to DNA extracted from liver  $(\triangle)$  and lung  $(\bigcirc)$  tissue of two normal baboons, and from the canine thymus cell line (FCf2Th) infected with baboon virus ( ). Self-annealing of the canine cell line (FC(2Th) unique sequence DNA (

<sup>3</sup>H-DNA probes were prepared from the viruses as described in Fig. 1. S-tropic murine virus<sup>14</sup> was grown in the canine thymus (FCf2Th cell line. Baboon C-type virus (M7)<sup>17</sup> was grown in the human rhabdomyosarcoma cell line (A204), and RD114 in RD cells<sup>13</sup>. Rat (R721C)<sup>14</sup> and pig (PK(15))<sup>8</sup> viruses were spontaneously released from their respective cell lines.

† Half C<sub>0</sub>t values represent the midpoint of the reannealing curves<sup>19</sup>. The reannealing rate of dog, baboon, human, cat, rabbit and mouse unique sequence cellular DNA has been shown<sup>13</sup> to range between a half C<sub>0</sub>t of 1.0 × 10<sup>3</sup>-2.0 × 10<sup>3</sup>.

‡ The cells are described in the legends to Figs 1 and 2. S2CL3 is a BALB/c cell line spontaneously producing mouse C-type virus<sup>32</sup>, and LIC-WRC256 is a rate carcinoma line producing rate C-type virus<sup>32</sup>.

LLC-WRC256 is a rat carcinoma line producing rat C-type virus<sup>32</sup>

§ These viruses do not replicate to any extent in any mammalian cell line tested.

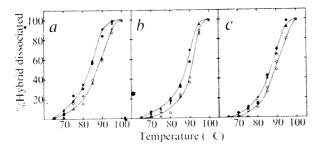

Fig. 2 Thermal stability of hybrids formed between viral <sup>3</sup>H-DNA probes and cellular DNA of various tissues and virus-infected cell lines. After hybridisation to a  $C_0t$  of  $10^4$ , aliquots (containing 600-1,200 c.p.m.) were heated for 5 min in 0.75 M NaCl at the indicated temperatures. The amount of hybrid remaining was determined with the single-strand-specific nuclease, S<sub>1</sub>. a, Thermal stability of hybrids formed between a <sup>3</sup>H-DNA probe prepared from the xenotropic (S-tropic) BALB/c virus<sup>14</sup> grown in a canine thymus cell line (FCf2Th) and DNA extracted from the S-tropic virus-infected canine cell line (O); the virusinfected rabbit cell line (SIRC)¹¹ (△); mouse liver (♠); and a BALB/3T3 cell line (♠). b, The ³H-DNA probe prepared from RD114 virus grown in RD cells¹⁵ was hybridised with DNA extracted from a canine thymus cell line infected with the endogenous cat virus, CCC (Ο); from a line of human embryonic fibroblasts (M413) infected with RD114 (Δ); from domestic cat liver ( ); and from either CCC CL6 or FFc60WF feline cell lines 31 (A). c, The 3H-DNA probe prepared from an endogenous baboon virus (M7) grown in the human rhabdomyosarcoma line A204<sup>17</sup> was hybridised with DNA extracted from the canine thymus cell line infected with M7 (○); from baboon liver (●); and baboon lung (A).

Table 1 summarises the half  $C_0t$  values obtained with  ${}^3H$ -DNA probes prepared from several mammalian C-type viruses. A human or canine cell line infected with the endogenous domestic cat virus, RD114, contains only one copy in the cell DNA (half  $C_0 t$  value is  $1.5 \times 10^3$  to  $2.0 \times 10^3$ ), whereas normal feline tissues and cell lines contain multiple copies of genes related to the information in this virus (the half Cot values range from  $1.8 \times 10^2$  to  $2.0 \times 10^2$ ). <sup>3</sup>H-DNA probes prepared from a porcine virus (PK(15)) and a rat virus (RT21C) were also hybridised, respectively, to the DNA of normal pig and rat. Again, multiple copies of these viral gene sequences are present in the DNA of their species of origin (half Cot values are  $0.6 \times 10^2$  to  $1.5 \times 10^2$ ). Since neither of these viruses can replicate in the mammalian cell lines so far tested, we cannot determine the reiteration frequency of the viral genes in exogenously infected cells. Each of the five mammalian species examined thus contains multiple copies of their endogenous virogenes. In striking contrast is the situation where a cell is infected with and actively producing a heterologous C-type virus; only one to two copies of the virus information is present in the cellular DNA.

Labelled DNA probes prepared from mouse leukaemia viruses (Kirsten and AKR) grown in mouse cells have also revealed multiple copies (five to seven) in mouse cell DNA6.7, as described here using probes from the xenotropic BALB/c virus grown in heterologous cells. Furthermore, the mouse mammary tumour viruses, B-type viruses, are also present in multiple copies in normal murine cell DNA<sup>20</sup>. The results described here for the five mammalian systems may not apply to the subgroup E endogenous chicken virus, where fewer viral copies (one or two) have been reported in normal tissues<sup>5</sup>. Some mammalian cells transformed by avian sarcoma virus, however, acquire one viral copy per haploid genome4, as do the cells infected with heterologous mammalian C-type viruses.

To examine whether the multiple copies of C-type viruses in the cellular DNAs of these mammalian species represented identical copies of one set of virogenes or a family of related sets of virogenes, the thermal stability of the hybrids was determined. Base-pair mismatching results in the formation of hybrids that melt at a lower temperature—the effect of mismatched base pairs on the thermal stability is between 0.7° C and 1.6° C per 1% altered base pairs19. Figure 2 shows the melting curves obtained when single-stranded <sup>3</sup>H-DNA transcripts of murine, RD114, and baboon C-type viral RNA were hybridised to the DNA from normal murine, cat and baboon tissues, respectively, and to the DNA of heterologous mammalian cells infected with these viruses. As Fig. 2a-c shows, the hybrid formed with DNA extracted from the species of origin of each virus melted 2-4° C lower than the hybrid formed with the DNA of a heterologous infected cell line. This result did not depend on the cell line in which the virus was grown; for example, the thermal stability data obtained with DNA extracted from either the canine or human cell lines infected with the endogenous cat viruses (RD114/CCC group) was higher than that obtained with various normal cat cellular DNAs. Thus, the multiple copies of C-type viruses in these mammalian species (murine, feline and baboon) were not all identical in sequence to the endogenous viruses isolated from these species.

What is the evidence that the various endogenous C-type viruses isolated from each of these species are different? In the murine system, three endogenous C-type viruses have been isolated from the BALB/3T3 cell line that differ not only in their host range but also in some of their nucleic acid sequences14,21. The C-type viruses from two rat cell lines (LLC-WRC256 and RT21C) share only a partial (40-60%) nucleic acid sequence homology (unpublished observations). We suggest, therefore, that the other mammalian species tested will also contain sets of virogenes which will be only partially related to the ones that have so far given rise to infectious C-type viruses.

The presence of multiple copies of viral information is a useful criterion with which to identify the species of origin of an endogenous mammalian C-type virus. A feline virus (RD114) satisfies this criterion, as do the mouse, baboon, rat and pig C-type viruses. Moreover, it is striking that the copy number clusters in a relatively narrow range (5 to 15 copies per haploid genome). Cells (including clonal isolates) and fresh tissues, to the extent that they have been examined, have comparable numbers of copies. These multiple copies of genetically transmitted C-type virus information may be present in the germ cells of each animal of a species (virogene hypothesis1) or they may evolve by recombination and gene duplication during the lifetime of the animal (protovirus hypothesis22). Taken together with experiments showing considerable expression both of viral RNA and viral specific proteins in embryos and various normal tissues<sup>23-26</sup>, the results described here suggest that C-type genes have been preserved selectively during evolution and that their expression has some normal physiological function. Whether during their evolution as cellular genes the virogenes of a single species have diverged from one another in function, as they have in structure, remains to be determined.

We thank E. Cusick, R. Heinemann, J. Koci and G. L. Wilson for help with these experiments. Supported in part by the Virus Cancer Program of the National Institutes of Health.

# Scanning immunoelectron microscopy of mouse B and T lymphocytes

ALTHOUGH B and T lymphocytes (derived from the bone marrow or thymus, respectively) are functionally different, they are not morphologically distinguishable by ordinary light and transmission electron microscopy (TEM). Thus immunospecific labels had to be developed for these methods to identify populations of lymphocytes1,2. Scanning electron microscopy (SEM) has been reported to show that T cells are smooth and B cells are villous3.4. This conclusion, however, is controversial, and it is uncertain whether T and B lymphocytes can be distinguished by SEM appearance5.6. We have now used immunospecific latex markers, which can be visualised by SEM, to identify cells with known T and B-associated antigenic surface determinants in the mouse. Mouse B cells have small stubby projections and are generally smoother than mouse T cells, which may be either villous or have few projections, but there is no distinct morphological difference.

An indirect latex labelling method, adapted from that of LoBuglio et al.7, was used to localise B-cell-associated and T-cell-dependent antigenic determinants on mouse lymphoid cells. The cells were treated with rabbit antisera to B or T-cellassociated antigens and then labelled with latex spheres coated with sheep anti-rabbit IgG (SARG). Rabbit anti-mouse Ig (B-cell-associated antigen, RAMG) was prepared by immunising rabbits with y-globulins precipitated twice with ammoniun sulphate and purified on DEAE. Rabbit anti-mouse brain (T-cell-associated antigen, RAMB) antiserum was prepared by immunising a rabbit with one brain equivalent in complete Freund's adjuvant (CFA) (Difco) in several subcutaneous sites boosting after I month and collecting the serum after a furthe month. The antiserum was heat-inactivated at 56° C for 45 min and absorbed with one-third volume packed mouse red blood

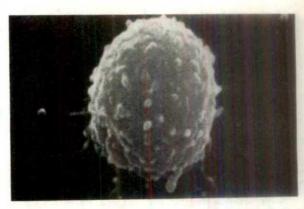

Fig. 1 Nu/Nu lymphocytes (B cells) sensitised with RAMB (T-cell-associated antigen). Cells were 5-7 µm in diameter and relatively homogeneous with a smooth surface. Usually 10-20 basal pseudopodial attachments and 50-100 micro-stubs covering the remaining surface could be visualised after attachment to glass. If the cells were treated with RAMB and followed by SARG-latex (see text), no latex label was visualised on the cell surfaces.

cells. Functionally, this antiserum plus complement remove all(1) helper cell activity for primary and secondary immun responses in mice, (2) concanavalin A and phytohaemaggluti mitogenic activity in mouse spleen populations and (3) cytotox effector cells, but had no detectable effect on plaque-formin cells, lipopolysaccharide mitogenic activity and precursor c memory B-cell populations as assessed by in vitro immur induction. SARG was prepared by immunising each of tw sheep with purified H chains of rabbit IgG in CFA intramu cularly. Booster injections were given and the sheep were ble 3 and 7 weeks later. The antisera were specific for IgG b immunoelectrophoresis and double diffusion in agar. Late particles nonspecifically adsorb y globulins, and latex sphere with adsorbed y globulin which has specific antibody activit will attach to the specific surface antigen7. One milligramme (

Nu/Nu lymphocytes sensitised with RAMG (B-cell associated antigen). Eighty per cent of cells treated with RAMB and SARG-latex (see text) show specific surface labelling for surface immunoglobulin (arrows). Usually a heavy background of latex particles (on the glass) accompanied positive labelling due to possible shearing and removal of surface label during preparation for SEM.

latex spheres (0.2 µm diameter) (Monsanto) was coated with 75 µl of SARG (SARG-latex) for 30 min at room temperature before labelling.

Mouse lymphocytes were prepared from the mesenteric lymph nodes of either congentially athymic, Nu/Nu, or BDFI mice. The lymph nodes were teased apart, cell aggregates were allowed to settle and then the cell suspensions were washed three times in basal salt solution. Functionally, Nu/Nu cells are primarily a B cell population<sup>8,9</sup>, and BDFI lymph node cells are a mixture of B and T cells; enriched T-cell preparations were obtained from BDFI lymph nodes by collecting the first 10 ml effluent fraction from a nylon wool column<sup>10</sup>.

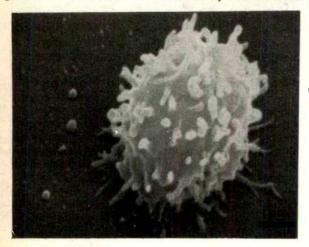

Fig. 3 BDF1 T cells sensitised with RAMG (B-cell-associated antigen). BDF1 lymphocytes (T cells) passed through the column showed heterogeneity in surface topographical characteristics. Usually 70–80% of the cells (5–7 μm in diameter) were villous, with 20–100 surface projections (50–800 nm long). The remaining 20–30% of the cells had smoother membranes, some without microvilli (not shown). If the cells were treated with RAMG and SARG-latex (see text), no surface labelling was seen.

Cell suspensions were prepared for latex labelling by settling 1-2×106 cells on to a 2 cm2 circular glass coverslip for 30 min at 37° C. The cells were fixed to the glass in 1% glutaraldehyde in 0.1 M cacodylate buffer, pH 7.2, for 30 min and rinsed twice in buffer. Sensitising or coating antiserum (RAMG or RAMB) was added for 30 min at room temperature and unreacted antiserum was rinsed off with PBS. Before addition of SARGlatex label, coverslips were rinsed in 0.2 M diphosphate, pH 9.2. SARG-latex was added for 30 min and unattached particles were washed off by flushing with 0.2 M diphosphate. The remaining antibody-ligated latex particles attached to the cell surface were stabilised by a second fixation in glutaraldehyde. γ Globulins (SARG) adsorbed on the latex particles may dissociate from the latex at low molarities and pH between 5.5 and 9.0, so that postfixation is needed to prevent dissociation of the latex from the cell surface. Even so, during SEM preparation the shearing forces on the large latex spheres may remove them from the cell surface, and we usually found many shed latex spheres with positive labelled cells. Labelled cells were dehydrated in a graded series of ethanol concentrations. The specimens were continued through Freon 113 and Freon 13 for critical point drying11, coated with 400 Å of palladium and examined on an ETEC U-1 scanning electron microscope with an accelerating voltage of 30 kV and specimen tilt of 30° or 45°.

SEM of labelled B lymphocytes (Nu/Nu cells) showed that they had a relatively smooth surface membrane, with prominent, stub-like digitations, but no distinct finger-like microvilli Figs 1 and 2). If B-cell preparations were sensitised (coated) with normal rabbit serum or RAMB antiserum followed by SARG-latex, no label was detectable on the surface (Fig. 1). However, surface immunoglobulin determinants could be visualised on 80% of the lymphocytes with SARG-coated atex if the cells were sensitised with RAMG (Fig. 2). Except

for the presence of label, there was no detectable difference between labelled and unlabelled cells. B lymphoyetes labelled for surface Ig had 50–150 densely distributed latex spheres attached to the surface. With specific labelling there were sometimes many free latex particles on the surrounding glass, probably due to shearing as above. The dense pattern of Ig labelling observed was different from the patchy and sparse distribution seen on rabbit peripheral blood lymphocytes (PBLs) which have quantitatively less surface Ig<sup>12</sup>. The unlabelled population of Ig-negative cells (20%) probably represented a null population or at least cells with insufficient surface Ig to be detected by this labelling technique.

Lymphocyte preparations enriched for T cells (eluted from nylon columns) were heterogeneous in surface topography. Between 70 and 80% were villous (Figs 3 and 4); the remaining 20-30% had smoother surfaces, some with few or no microvilli. Latex label could not be detected on T-cell-enriched preparations sensitised with normal rabbit serum or RAMG followed by SARG-latex (Fig. 3). Specific cell surface labelling, however, was visible on more than 90% of cells sensitised with RAMB (Fig. 4). The label was usually seen as distinct patches (1-2 μm across) containing 5-15 spheres. Most villous cells had quantitatively more surface label than smoother cells. Because differences in morphology may be due to cell preparations, for example, elution off a nylon wool column may induce formation microvilli in a subpopulation of T cells, we examined normal unfractionated BDF1 lymph node cells. Of these 30-40% were labelled with RAMB and SARG-latex. The morphology of the labelled cells was similar to that of the T-positive cells (90%) in the T-enriched population (that is, most of the labelled cells were villous), suggesting that nylon column fractionation did not affect significantly the surface architecture of the passed cells. The observed differences in T-cell morphology and labelling may represent different functional populations, especially since the more villous cell types had more T-specific surface label.

Cell preparation and processing for SEM may affect the surfaces of mouse lymphocytes. Rabbit PBLs are smooth in suspension by SEM and TEM, but develop microvilli and pseudopodia when adherent to glass for SEM<sup>13</sup>. In the study reported here all cells were allowed to adhere to glass for 30 min to produce conditions for villous formation. Environmental factors, including temperature<sup>14</sup>, cell preparation<sup>15</sup> and cell cycle<sup>16</sup> can affect the topology of the surface membrane. Thus these parameters must be evaluated before the SEM appearance of individual cells can be used for identification.

The controversy of 'hairy' B cells and 'smooth' T cells is unresolved. Contrary to our findings, with mouse lymphocytes,

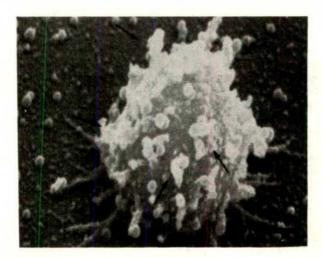

Fig. 4 BDF1 T cells sensitised with RAMB (T-cell-associated antigen). T lymphocytes treated with RAMB and SARG-latex (see text) showed specific surface labelling of brain associated (T-dependent) antigen. Latex label was visualised on 90% of the cells as distinct patches (arrows).

SEM observations of human lymphocytes showed that B cells usually had numerous microvillous projections, whereas T cells were smooth with relatively few microvilli3.4. In our experiments mouse B cells were relatively smooth, while most T cells had extensive microvilli and pseudopodia. We interpret these morphological distinctions with caution because there is usually a great deal of heterogeneity in surface architecture among a given population of cells. Even in our enriched population of T cells, a wide variety of positive labelled stubby and villous cells was found. Thus, we conclude that B or T cell identification by SEM is tenuous without immunospecific markers.

RAMB antiserum was a gift from Dr Max Slomich. This work was supported by grants from the US Public Health Service, the National Institutes of Health and the American Cancer Society.

# Haemagglutinins in commercial preparations of monosaccharides

We have found that several commercial preparations of monosaccharides possess haemagglutinating activity. This activity was observed with monosaccharide concentrations close to those usually used to inhibit the biological effects of lectins. The activity is not due to the monosaccharides themselves but is associated with a high molecular weight compound(s) active in some preparations of monosaccharides.

Soybean agglutinin was purified by affinity chromatography as described previously<sup>1</sup>. Human erythrocytes, drawn into EDTA and used within 7 d, were washed four times with phosphate buffered saline (PBS), pH 7.2-7.4, trypsinised as 4% (v/v) suspensions in PBS with 0.01% (w/v) crystalline trypsin (Sigma, type XI) for 90 min at 37° C and washed again

Agglutination of type O, trypsinised human erythrosuspensions in Microtiter wells) by soybean agglutinin and by N-acetyl-D-galactosamine and D-galactose. Four titrations of soybean agglutinin as serial twofold dilutions in PBS or PBS plus monosaccharide are shown. The soybean agglutinin concentration in the first well of each titration series (A-1, C-1, E-1, G-1) was 1,000 μg ml<sup>-1</sup>. The twenty-first and twenty-second wells of each titration (B-11 and B-12, D-11 and D-12, F-11 and F-12, H-11 and H-12) were controls and contained no soybean agglutinin. In the first titration (A-1 through B-10), no monosaccharide was present. The wells of the second (C-1 through D-10), third (E-1 through F-10) and fourth (G-1 through H-10) titrations of soybean agglutinin and the wells of their respective controls contained 0.01 M N-acetyl-p-galactosamine (Pfanstiehl, lot no. 8076A), 0.01 M p-galactose (Pfanstiehl, lot no. 9145), and 0.01 M p-galactose (Baker, lot no. 2-0411), respectively.

four times with PBS. Haemagglutination assays were performe as described previously2 in unperturbed wells of Microtite plates (Cooke Engineering Co.) with 1% (v/v) erythrocyt suspensions and twofold serial dilutions in PBS of the aggle tinin of interest. The sedimentation patterns of the 1% erythro cyte suspensions were read after 2 h at room temperature. positive pattern, indicating agglutination, is uniform effacement of the bottom of the well by erythrocytes; a negative pattern indicating no agglutination, is a circular clump of erythrocyte surrounded by a concentric, clear zone (Fig. 1).

Our initial observation was that some preparations inhibitory sugars produced positive haemagglutination pattern in Microtiter wells with concentrations of soybean agglutini insufficient for agglutination (Fig. 1). As expected, soybea agglutinin-mediated haemagglutination was inhibited N-acetyl-D-galactosamine and by two preparations of galactose. It was unexpected that two of the three inhibitor monosaccharides tested. N-acetyl-p-galactosamine (Pfanstieh lot no. 8076A) and p-galactose (Pfanstiehl, lot no. 9145), cause haemagglutination (wells C-10 through D-12 and E-10 through F-12, respectively) when the concentration of soybean aggle tinin was too low for hacmagglutination. No agglutination w produced by agglutinating preparations of N-acetyl-p-galacte samine or p-galactose in the presence of high concentrations soybean agglutinin (wells C-1 through C-8 and E-2 through E-8 Therefore, it seems that some interaction between soyber agglutinin and the agglutinating compounds present in the monosaccharide preparations prevented haemagglutination l the agglutinating compounds. The nature of this interaction not understood; the haemagglutinating material may bind soybean agglutinin. The interaction is obviously not inhibite by the parent monosaccharide solution. A similar phenomene was observed with p-mannose and concanavalin A (Mile Yeda).

Preparations of these and other monosaccharides we surveyed for haemagglutinating activity in the absence of lecti (Table 1). Since not all preparations of D-galactose an N-acetyl-p-galactosamine caused haemagglutination, we con clude that the haemagglutinating activity is not due to the

monosaccharides but must be produced by another compound active in some preparations.

We have investigated the nature of the haemagglutinating compound present in D-galactose (Pfanstiehl, lot no. 9145). Trypsinised erythrocytes were about ten times more susceptible to agglutination than were non-trypsinised erythrocytes; types A, B and O erythrocytes were equally agglutinable. Agglutination was not totally reversed by nine washes of the agglutinated erythrocytes with 100-fold volumes of PBS. Haemagglutinating activity was removed from a 0.2 M galactose solution by preincubation for 2 h at room temperature with 5 × 10<sup>7</sup> type O erythrocytes per ml. The haemagglutinating activity in the sugar solution was destroyed by boiling for 90 min; the activity was resistant to up to ten cycles of freezing and thawing.

The haemagglutinating activity in galactose (Pfanstiehl, lot no. 9145) was found in the retentate and could be concentrated quantitatively and washed free of monosaccharide by ultrafiltration over an XM-50 ultrafilter (Amicon) which nominally retains proteins of molecular weight greater than 50,000. The activity was nearly completely retained by an XM-300 ultrafilter that retains proteins of molecular weight greater than 300,000. The haemagglutinating activity in solutions of p-mannose (Baker, lot no. 1-9855) and D-glucose (Mallinckrodt, lot no. XDX) could be separated in a similar fashion.

Preliminary characterisation of the concentrated compound, washed free of D-galactose by ultrafiltration indicated that the compound had a high carbohydrate content by the phenolsuphuric acid assay3. A Lowry determination4 indicated a protein content equivalent to 90 µg of bovine serum albumin per mg of dried material, but the carbohydrate content may have interfered with the procedure5; preliminary analysis revealed only trace amounts of amino acids. Ultraviolet spectra of agglutinating preparations of unfiltered p-galactose (~ 0.2 M) show a peak at 280 nm (~ 0.25 absorbance units). The material responsible for the absorbance could be removed partially by ultrafiltration, however, without demonstrable loss of haemagglutinating activity. Possible sources of these high molecular weight haemagglutinating compounds are the

Haemagglutinating activity was assayed in Microtiter plates with a 1% suspension of trypsinised, type A erythrocytes and serial twofold dilutions of the monosaccharides in PBS as described in the text. The lowest millimolar concentrations of monosaccharides producing haemagglutination are shown. The highest concentration tested was 160 mM. The sources and lot numbers are indicated in parentheses.

-fucose (Pfanstiehl 9698ML)

lucrose (Baker 30388)

biological source of the sugar (for example, ivory-nut meal for mannose6), biological agents used during production of the sugar (for example, bakers' yeast for galactose7), and polymerised products of sugars and/or sugar derivatives8 formed during manufacture and purification of the sugar. Heatpolymerised furfurals8 do not appear to be responsible for the haemagglutinating activity as atmospheric refluxing of aqueous solutions of galactose and glucose sufficient to produce intense ultraviolet absorption at 280 nm did not produce haemagglutinating activity. We conclude tentatively that the haemagglutinating material obtained from galactose is a heat labile macromolecule composed primarily of carbohydrate with, perhaps, a minor protein component.

The presence in many monosaccharide preparations of a large molecular weight compound with haemagglutinating activity may have important consequences for several kinds of studies on the biological effects of monosaccharides, and for studies of any biological system containing or utilising monosaccharides. Such considerations are of obvious importance in tissue culture where glucose is a component of culture media and in studies involving the effects of monosaccharides on tissue culture cells and intact organisms as, for example, in sugar transport9. The presence of these compounds in monosaccharides may affect sugar-dependent characterisation of the physical properties and biological specificities of lectins and even the purification of lectins by affinity techniques utilising monosaccharides. Until the properties of these high molecular weight compounds are more fully understood, ultrafiltration can be used for complete removal of the high molecular weight compounds and the associated haemagglutinating activity from the monosaccharides.

## Molecular and crystal structure of deoxyguanosine 5'-phosphate

RECENT crystallographic studies of the dinucleosides ApU (ref. 1) and GpC (ref. 2) have given experimental proof for the base pairing arrangement proposed by Watson and Crick for the DNA double helix3. Another striking feature of this structure relates to the torsional angle about the C5'-C4' bond in the phosphate-sugar backbone chain. In the Crick and

Watson model4, this conformation is gauche-trans (GT). Crystal structures of 5'-nucleotides, dinucleosides and dinucleotides so far studied, however, have shown only the gauchegauche (GG) conformation about this bond. The GG conformer is also the only one found in the refined models of the proposed structure of the double helical nucleic acids and polynucleotides<sup>5-7</sup>. The only nucleotide with a GT conformation is 6-azauridine-5'-phosphate8 which is not a normal monomer unit of nucleic acids. It is also reported that 5'-dGMP assumes preferentially GT conformation in solution9.

We wish to report here the molecular structure of the DNA monomer unit, deoxyguanydilic acid (dGMP-5') as determined by a complete three-dimensional X-ray structure analysis. The nucleotide shows the GT conformation about the C-5'-C-4' bond similar to that occurring in the Crick and Watson model.

Crystals of the disodium salt of deoxyguanosine 5'-phosphate were grown by slow diffusion of alcohol into aqueous solutions of the compound<sup>10</sup>. Thin platty crystals about 2 mm long were obtained in about 3 week. The crystal belongs to monoclinic system with space group P2<sub>1</sub>. The unit cell dimensions are a = 16.00 Å; b = 10.73 Å; c = 5.575 Å;  $\beta = 101.9^{\circ}$ ;  $d_{obs} = 1.64$  g cm<sup>-2</sup>;  $d_{cal} = 1.64$  g cm<sup>-2</sup>; Z = 2. Density measurements carried out using carbon tertachloride-bromoform mixtures indicated the presence of four water molecules in the asymmetric unit. Intensity data were collected by multiple film, equiinclination, Weissenberg technique for hO1-h91 and hkO layers using CuK, radiation. The data were measured visually by comparison with precalibrated graded intensity scale. A three-dimensional Patterson function was computed and the phosphorous atom was located from the Harker section. The structure was solved by symbolic addition

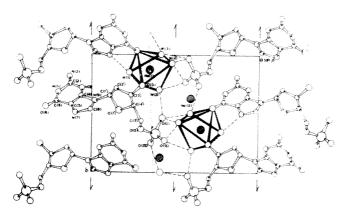

Fig. 1 Structure of dGMP-5' Na<sub>2</sub> 4H<sub>2</sub>O viewed down c axis. One of the sodium atoms (Na(1)) has an octahedral coordination shown by thick lines. Hydrogen bonds are indicated by broken lines. The stacking pattern of the bases belonging to molecules related by a 'c' cell translation is not shown for the sake of clarity.

method. Phases for 290 reflections were obtained using the program 'Multan'11. An E map was computed for the best set which gave a Karle R factor for 28.59%. The entire molecule with two sodium ions and one water oxygen atom were identified from the E map from a knowledge of the position of phosphorous atom and by model building approach. The current structure has an R factor of 9.0%. The view of the structure down c axis is given in Fig. 1.

The glycosidic torsional angle  $\chi_{CN}$  is 52.6°. The relative orientation of the base with respect to the sugar is therefore, anti. The  $\chi_{CN}$  value is within the range expected of  $\beta$ -purine nucleotides. The best four atom plane for the deoxyribose moiety passes through C1'-C2'-C3'-C4'. The O1' atom shows an endo puckering, being displaced by 0.6 Å from this plane in striking contrast with the other three DNA monomers where the furanose ring is puckered either with C2' or C3' (refs 12-14).

The conformation about the C5'-C4' bond is GT with

 $\phi_{\mathbf{O5'}-\mathbf{O1'}}=62.5^{\circ}$  and  $\phi_{\mathbf{O5'}-\mathbf{C3'}}=174.8^{\circ}$ . As mentioned earlie this is the first structure to show this conformation which i close to that found in Watson-Crick DNA model ( $\phi_{ns} = 38$  $\phi_{oc}=155^{\circ}$ ).

In model building studies and refinement on nucleic act structures one tends to use the structural parameters an torsional angles within the constraints prescribed by the result of single crystal X-ray studies on flucleic acid constituents. I seems to us that the conformational features observed i dGMP-5' have also to be considered in possible polynucleotid conformations and foldings particularly of the DNA. Th GT conformer and the O1' endo puckering of sugar ring are als of direct relevance to the concept of rigid nucleotide unit25.

We thank Professor V. S. Venkatasubramanian for hi interest and Dr K. Venkatesan and Mr S. Ramakumar fo providing the modified version of the 'Multan' program T.P.S. thanks the UGC authorities for financial support. Note added in proof:- An accurate independent X-ray analysis of this nucleotide has now been reported by Young, Tolli and Wilson<sup>16,17</sup>. Our findings are in close agreement with th

#### Errata

In the article "Volatilisation of mercury and organomer curials determined by inducible R-factor systems in entering bacteria" by J. Schottel et al. (Nature, 251, 335; 1974), it the last two lines of the legend to Fig. 1 and also in the penultimate line of para. 3, J53(471a) should read J53(R471a) on each occasion.

In the article "Subunit structure of chromatin" by M. No. (Nature, 251, 249; 1974) line 7 of the legend to Fig. should read '... and  $V_m=9.2$  ml in 0.2 mM ... ' and no as originally printed.

# matters arising

### Do molecular biologists come of age in Aries?

WINDSOR has concluded that, "More molecular biologists were born under the sign of Aries than any other sign. More taxonomists were born under the sign of Cancer than any other sign and relatively few were born under Scorpio." Lest acceptance of these findings induces prospective parents to time the birth of their offspring to maximise their chances of becoming molecular or taxonomic biologists, a modest statistical analysis of Windsor's data seems in order

Table 1 contains the frequencies, arranged by Sun sign and biological bent, of the birthdates of 812 biologists in the sample observed by Windsor1. The relative frequencies of births for the general population of the United States for 1934 by Sun sign were estimated by adding the products of the monthly relative frequencies by the respective fraction of each of the two months contributing to a given Sun sign interval as given by Parker and Parker<sup>2</sup>.

In the  $\chi^2$  tests for goodness of fit to the data in Table 1, the critical value is  $\chi^2_{0.05,11} = 19.675$  if  $P \le 0.05$  is the signicance level to reject the null hypothesis, Ho: that each sample has the same frequencies as the general population. Since  $0.75 \le P(\chi^2 \ge 7.282) \le 0.90$  for the taxonomists,  $0.10 \le P(\chi^2 \ge 16.368)$ ≤ 0.25 for the molecular biologists, and  $0.25 \le P(\chi^2 \ge 11.580) \le 0.50$  for the combined sample of 812 biologists, the null hypotheses cannot be rejected. That the samples of taxonomists and molecular biologists could have come from the same population is confirmed by the heterogeneity  $\chi^2$  test:  $0.25 \le P(\chi^2 \ge 12.070) \le$ 0.50.

As might be expected, the same conclusion that the biological discipline of the 812 scientists is independent of the Sun sign of birth is borne out by a  $2 \times 12$ contingency table3,4 which involves no assumptions about the birth frequencies per Sun sign for the general population. In this case,  $0.25 \le P(\chi_{11}^2 \ge 11.495) \le$ 0.50.

Even if the  $\chi^2$  tests had permitted the rejection of the null hypotheses, the validity of Windsor's conclusions would have been restricted to biologists in American men and women of science<sup>5</sup> whose birthdays were listed. Other factors such as age and sex proportions among axonomists, molecular biologists, and the general population would have complicated analysis and interpretation even further.

Table 1 Frequencies (f) of birthdates by Sun sign from a sample of 812 biologists<sup>1</sup> and expected frequencies (F) if the proportions were the same as in the general population (see text)

5 American men and women of science: the physical and biological sciences, twelfth ed. (edit. by Jacques Cattell Press), 1-6, (Bowker, New York, 1971-73).

DR WINDSOR REPLIES-Dr Colás certainly provides an appropriate criticism of my Sun sign findings.

The statistical method I used, before publication, was a non-parametric analysis of a manifold population as described by Tate and Clelland<sup>1</sup>. Considering the 12 Sun signs as a manifold population, the hypothesis tested was that the distribution of birthdays was uniform,  $H_0 = Ar = T$ = G ... = P = 1/12.  $\chi^2 = [(f^0 - f^e)^2]/f^e$ , where  $f^0$  is the frequency of characters in the sample and  $f^{e}$  is the frequency expected under the null hypothesis, that is, the average.

 $\chi^2 = [(Ar - f^e)^2]/f^e + [(T - f^e)^2]/f^e +$  $[(G-f^e)^2]/f^e ... + [(P-f^e)^2]/f^e.$  $\chi^2$  for molecular biologists = 13.818;  $\chi^2$ for taxonomists = 8.666. At 11 degrees of freedom the probabilities of the hypotheses being true are 0.025 and 0.600, respectively. Since the hypothesis is rejected in both cases, therefore, the distributions were not random.

I compared molecular biologists with themselves and I compared taxonomists with themselves. I did not compare them with each other or with the general population. Molecular biologists and taxonomists are simply different kinds of biologists and must be considered independently or else the distinction is lost. Comparing them with the general population is unnecessary because it is obvious that, for the most part, they did indeed come from the same general population. The problem is not to identify similarities and establish origins, but to separate components and identify their characteristics. I used American men and women of science as my data base because it is a readily accessible, reproducible sample. Its validity can only be determined by gathering additional data. To cite one instance of possible invalidity, many practising molecular biologists are probably not listed as such, but appear classified as biochemists or physiologists, since the scientists describe their own disciplines.

My data were, admittedly, meagre, but it was hoped that their publication would inspire, or even goad, scientists with more resources to pursue this line of research by acquiring and analysing larger data bases. The basic concept of extraterrestrial influences on human activities is so important that it certainly deserves much more investigation than is now being performed.

# Ascorbic acid and nitrosamines

EDGAR<sup>1</sup> has proposed that ascorbic acid might inhibit the carcinogenic action of nitrosamines and other carcinogens that may act by alkylation. The rationale was that ascorbate might be alkylated *in vivo* before the carcinogens can react with cell macromolecules. The experimental basis for Edgar's thesis was the statement by Kamm *et al.*<sup>2</sup> that ascorbate inhibited the liver necrosis induced by dimethylnitrosamine (DMN). This statement, however, was presented without experimental details and was subsequently withdrawn<sup>3</sup>.

The main concern of the study by Kamm et al. was the inhibition by ascorbate of the liver toxicity induced by oral administration of aminopyrine plus nitrite. This study followed our report in 1972 suggesting, on the basis of in vitro experiments, that ascorbate might be used to block in vivo formation of Nnitroso compounds from nitrosatable chemicals (for example, drugs), since ascorbate efficiently reduces nitrite4. Subsequently, the report by Kamm et al.4 appeared. Greenblatt<sup>5</sup> found similar results in mice to those of Kamm et al., but stated that ascorbate did not affect DMN toxicity. We found that ascorbate prevented liver damage from gavage of dimethylamine plus nitrite to rats and, from experiments presented in detail, that ascorbate did not significantly affect the production by DMN of liver necrosis and elevated serum transaminase levels6 Ascorbate did not affect transplacental carcinogenesis in rats by ethylnitrosourea, but inhibited carcinogenesis by ethylurea plus nitrite7.

We are concerned that our original suggestion should not be extended without basis to the hypothesis that ascorbate might have a much wider inhibitory action on carcinogens. The interesting suggestion of Edgar is not supported by the results reviewed here, which were mostly made public after Edgar's paper was submitted.

Scrapie

In a group of Herdwick sheep genetically selected for susceptibility to subcutaneous injection with SSBP/1 scrapie brain pool, Pattison reported¹ the occurrence of two cases in uninjected animals. He concluded "... that these two cases arose spontaneously by genetic selection". The simplest explanation of these two cases, however, is that they were due to infection with scrapie from some unrecognised source with later cases resulting from lateral and maternal transmission of the infection.

The factual parts of Pattison's report are in accord with our own findings. Cheviot sheep have been selected successfully for increased or decreased susceptibility to scrapie2,3 following subcutaneous injection with the same source of agent as that used by Pattison. These Cheviot sheep were bred on a geographically isolated farm, away from known cases of scrapie and for the first 7 yr no natural cases of scrapie occurred. Since 1968, however, when a natural 2-yr-old case occurred in the positive selection line, the incidence of natural cases has built up as shown in Table 1, and 81 of the 83 cases have occurred in the positive line. The other two cases have occurred recently in a group of 11 positive-line × negativeline crosses born in 1970. As in Pattison's cases these natural Cheviot cases are

easy to distinguish on histological criteria. Because many different strains of scrapic agent can be recognised by the characteristic type, severity and distribution of brain lesions which they produce<sup>4</sup>, the histological difference found in the sheep is direct evidence that no component of SSBP/I is involved in the natural Cheviot cases and this is supported by a failure so far to isolate from them either 22A, 22L or 22C (three strains of agent known to be present in the SSBP/I pool<sup>5</sup>).

The simplest explanation for the occurrence of the natural Cheviot and Herdwick cases is that the necessary conditions for the total 'isolation' of a flock from direct or indirect contact with scrapie agent are not yet understood. This is not surprising in view of the well known extreme resistance of scrapie agents to physical or chemical inactivation. Also, Icelandic evidence supports the view that there can either be long term persistance of scrapie infectivity on farms in the absence of sheep or that some vector is involved (ref. 6 and P. A. Palsson and B. Sigurdsson, unpublished). Quite apart from these considerations scrapie is known, quite definitely, to be naturally transmitted both laterally and maternally in field conditions (refs 7 and 8 and J. L. Hourrigan et al., unpublished) and among housed sheep<sup>8-12</sup>.

One comment is fundamental; is should not be assumed that the Herdwick; and Cheviots which are susceptible to peripheral injection with SSBP/1 scrapic will be susceptible to all strains of scrapic or that the resistant lines will be resistant to all strains. Such an assumption is at the basis of Pattison interpretation. The situation is clearly illustrated by work with scrapic in mice where it is not possible to describe on genotype as susceptible and another a resistant unless the strain of scrapic agent dose of agent and route of infection are specified 13.

Although the work with the Chevic sheep is less advanced than that in mice there is evidence that a similar situatio applies in both species. Pattison extes hi own report of scrapic infectivity bein produced from apparently normal mous tissue: these results were interpreted bhim as evidence for spontaneous generation of scrapic infectivity ('unmasking

### Ageing cell cultures

Is there an irreversible loss of mitotic ability in mammalian cell populations during ageing<sup>1</sup>? The results of continuous labelling alone can neither confirm nor refute this hypothesis.

Macieira-Coelho<sup>2</sup> continuously labelled cultures of human embryonic fibroblasts with tritiated thymidine. He found that the proportion of unlabelled cells declined to zero in a convex fashion. His result is an inevitable consequence of the continuous labelling method.

Macieira-Coelho did not distinguish between unlabelled dividing cells and unlabelled non-dividing cells. By definition non-dividing cells will not take up label and will not reproduce. If the initial proportion of unlabelled nondividing cells is  $q/2^{\circ}$ , then after k population doublings this proportion will be reduced to  $q/2^k$ . The proportion of unlabelled dividing cells will decline at a faster rate since the number of dividing cells that are unlabelled also will decrease. The proportion of unlabelled cells is the sum of these two proportions. It will decline to zero in a convex fashion (Table 1).

It will decline whether time is measured, chronologically, in population doublings, in split ratios or in cell generations<sup>3</sup>. It will decline whether the population is growing or static, for in a homeostatic population, where cell death is balanced by cell birth, the number of unlabelled cells will decline. It will decline whether or not un-

labelled cells continue to enter the division cycle.

The results reported by Macieira-Coelho<sup>2</sup> are artifacts of the continuous labelling method.

- <sup>3</sup> Good, P. I., Cell Tissue Kinet., 5, 319 (1972).
- <sup>4</sup> Smith, J., and Hayflick, L., J. Cell Biol., 62, 48 (1974).

DR MACIEIRA-COELHO REPLIES—I think the theoretical speculations made by Dr Good are more likely to be artifacts than the experimental results on which I have based my conclusions.

Dr Good says that the decline in the population of unlabelled cells is an inevitable consequence of the continuous labelling method. As a matter of fact, my data show very clearly that this is not the case, and that the proportion of unlabelled cells depends on the size of the inoculum. With high inocula not all the cells have time to enter the cycle before division stops due to cell crowding. Furthermore, if after a continuous labelling one finds only 6% of unlabelled cells, regardless of how this equilibrium is reached at resting phase (loss of non-dividers, dilution, and so on) it means that there are only 6% of cells which did not enter the S period. The possibility remains that these cells are slowly cycling cells delayed in other periods, a hypothesis most mathematicians do not like to consider.

Eight years ago I published results' which led to the conclusion that during the growth decline of human fibroblasts the cell population becomes strongly heterogeneous and the cells show a spectrum between the two extremes, that is, complete inhibition of division and the normal division cycle. What has to be kept in mind is the presence of a spectrum, and the experimental evidence suggests that there is no predominant cell type (that is, cells with fast, intermediate or long generation times, or non-dividers). If there is a fraction of cells which do

not divide at all in the population, this is a small fraction as my data have now shown. There is no reason whatsoever to make speculations about growth kinetics stating that this small fraction would play a bigger role than the rest of the spectrum of cells with a whole range of generation times.

### Intelligence and handedness

GIBSON¹ has stated that his data do not support Levy's² contention that left-handed subjects have significantly lower visuospatial IQ's. Cohen's³ factorial study of the Weschler adult intelligence scale suggests that a more appropriate test of verbal IQ than the full Weschler scales used by both Gibson and Levy would consist of the average of age-weighted scores on subtests weighting on verbal comprehension (information, comprehension, similarities, vocabulary) and a test of visuospatial IQ would consist of subtests weighting on perceptual organisation (block design, object assembly).

Table 1 Comparison of two measures Right handed handed 125.5 7.08 mean 123.3 Verbal IQ s. d. 5 36 112.7 mean 114.6 Performance IQ 6.72 6.82 s. d. Verbal comprehension 14.78 score mean 1.37 1.27 s. d. Perceptual organisation 12 37 12.4 mean score 3.54 s.d. 1.60

Comparing a small sample of left- and right-handed subjects, ten of each group, no significant differences between the two groups were found on either the full verbal and performance IQ's or on the verbal comprehension and perceptual organisation scores (Table 1). These data support Gibson's findings.

L. D. ROBERTS

Department of Psychology, University of Bradford, Bradford, Yorkshire BD7 1DP, UK

- Gibson, J. B., Nature, 243, 482 (1973).
- <sup>2</sup> Levy, J., *Nature*, **224**, 614 (1969).
  <sup>3</sup> Cohen, J., *J. Consult. Psychol.*, **21**, 451

DR GIBSON REPLIES—A reanalysis of my data along the lines suggested by Roberts has given similar results. There are no significant differences between left-handed and right-handed subjects on either the verbal comprehension or perceptual organisation scores.

#### APPOINTMENTS VACANT

#### ASSISTANT PROFESSOR IN **PALEONTOLOGY** UNIVERSITY OF TORONTO

Ph.D. required from July 1, 1975, with teaching and research interests in invertebrate paleontology or micro-paleontology and its stratigraphic applications. Duties include undergraduate and graduate teaching, development and maintenance of a research programme, and supervision of graduate students. Salary dependent on qualifications and experience. Address enquiries to Dr. D. W. Strangway, Chairman, Dept. of Geology, University of Toronto, Toronto, Ontario MSS 1A1, Canada, (1591)

#### UCLA

University of California, Los Angeles, Department of Geology invites applications for two-year faculty appointments as assistant professor. A Ph.D. is required. Two faculty two-year positions will be available beginning September 1975. Applicants must have truly superior capabilities in one or more of the relevant basic physical or biological sciences. Two earth scientists will be selected from the three following general areas:

(1) Those engaged in research in the content of the relevant basic physical or biological sciences.

(1) Those engaged in research in one or more of the fields (a) igneous or metamorphic petrology; (b) ore genesis; (c) experimental or theoretical geochemistry; (d) mineral physics. Examples of emphasis include thermodynamics of irreversible processes and chemical or thermal diffusion.

(2) Those engaged in research in the areas of tectonophysics, geological physics, or structural geology. Of particular interest are: (a) solid-state aspects of microscopic phenomena-fracture and flow of rocks, diffusion, thermodynamics, and lattice dynamics; (b) global tectonics; (c) quantitative modelling of large or small scale processes.

(3) Marine science, those engaged in research in organic geochemistry, ecology, or marine geology. Examples of emphasis include diagenesis of sediments, interstitial water, evolution, phycology (calcarcoss algae), invertebrate biology, and global tectunies. tectonics

Clarence A. Hall, Chairman
Department of Geology
University of California Los Angeles
Los Angeles, California 90024

Minority and ethnic earth scientists are encouraged to apply. UCLA is an affirmative-action/equal opportunity employer. (1654)

#### UNIVERSITY OF LIVERPOOL CHAIR OF HISTOLOGY AND CELL BIOLOGY (MEDICAL)

Applications are invited for the Chair of Histology and Cell Biology (Medical), within the Faculty of Medicine, which will become vacant on April 30, 1975, following the retirement of Professor N. M. Hancox, It is not a requirement that the holder of the Chair should possess a medical qualification.

the Chair should possess a medical qualification.

The salary will be within the range approved for full-time professorial appointments and in any case not less than £6.264 per annum.

Applications (12 copics), together with the names of three referees, should be treceived not later than November 29, 1974 by the undersigned, from whom further particulars may be obtained. (Candidates overseas may send one copy only, by airmail). Quote ref. RV/N/300.

H. H. Burchnall,

H. H. Burchnall, Registrar. (1749)

### LEICESTERSHIRE AREA HEALTH AUTHORITY (T) AREA MEDICAL PHYSICS DEPARTMENT

Applications are invited from Graduates for a newly established post in the Leicestershire Medical Physics Department. This department which is undergoing considerable expansion, provides a service for the

# **Electronic Engineer or Physicist** Senior or Basic Grade

A vacancy exists for an experienced Physicist or Electronic Engineer to set up an Audiological testing section involving clinical work,

This post will provide scope for developmental work in which the successful applicant will be encouraged to participate. Opportunities will occur for him to be engaged also in other aspects of Medical Physics at the Leicester Royal Infirmary.

Applicants should have a good honours degree in electronic engineering or physics with a special interest in electronics and experience in this field would be desirable, though not essential.

Salary on scale: Senior £3,345 to £4,377 p.a. • Basic Grade £2,046 to £2,994 p.a.

Further information from the Principal Physicist in Charge,

Applications stating age, experience and qualifications with the names two referees to the Hospital Secretary, The Leicester Royal Infirmary, Infirmary Square, Leicester.

Closing date for applications (November 18, 1974).

(1758)

# MINE GEOLOGIST

Applications are invited for the post of Mine Geologist to serve a group of Collieries in the Western Area of the National Coal Board. The successful candidate would be responsible for recording geological information and participating in investigations into the effects of geological environment on mining operations. The work will mainly involve underground duties.

Applicants should have an Honours Degree in Geology. Training in underground geological techniques will be given to the successful candidate.

Starting salary, in accordance with qualifications and experience, within the scale £2,345 to £2,885.

Write for application form to Area Staff Manager, National Coal Board, Staffordshire House, Berry Hill Road, Stoke-on-Trent. (1795)

Ministry of Overseas Development Centre for Overseas Pest Research, London

- To work on the identification and determination of pesticides in samples of water, soils, crops and animals collected in overseas
- □ Degree, HNC or equivalent in Chemistry □ Experience in Chromatography or pesticide residue analysis desirable 
  Age under 30 
  Appointment
- as Higher Scientific Officer (over £2800 to around £3750) or Scientific Officer (over £1950 to around £3050)  $\square$  Ref: SA/21/JA.  $\square$  Application forms (for return by 28 November 1974), from Miss M B McKiernan, Ministry of Overseas Development, Centre for Overseas Pess. Research, College House, Wrights Lane, London W8 58J.

(1834)

### NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the post of:

# TREE PHYSIOLOGIST

Applicants must have a postgraduate degree or experience in tree physiology and research experience in decays of timber or decay in standing trees. Experience in tropical pines and eucalypts also desirable.

Excellent laboratory facilities and equipment exist to carry out physiological research. The appointee will be required to carry out research on the physiology of tropical pines and eucalypts of economic importance in Zambian forestry.

Salary according to qualifications and experience but a higher salary would be offered to exceptionally well-qualified and experienced senior scientists.

Professional Officers
Senior Professional Officers

K3,240 by K240 to K4,440 K4,680 by K240 to K5,640

Principal Professional Officers

K5,840 by K240 to K6,800

For Zambians there is a superannuation scheme. Non-Zambians will be paid a gratuity of 25 per cent of aggregate basic salary earned during service of not less than thirty months.

Accommodation will be provided on an economic rental basis but not exceeding 10 per cent of basic salary. Hard furniture will be provided. For Non-Zambians travel and educational allowances are available for minor dependent children attending school outside Zambia.

Applications giving full personal details, qualifications, experience and naming three referees should be submitted to:

The Secretary-General, National Council for Scientific Research, P.O. Box CH. 158, Chelston, LUSAKA, Zambia.

(1762)

#### **BIOCHEMIST**

Ph.D. or equivalent. Must have laboratory experience in vitamin D chemistry or action. To establish a vitamin D-focused laboratory programme in conjunction with university calcium researchers. Position at Research Institute. The Hospital for Sick Children, Toronto, with faculty appointment in Department of Biochemistry, University of Toronto. Salary commensurate with experience and qualifications. Apply before December 1st enclosing curriculum vitae and names of two referes, to:—The Secretary, Research Institute, The Hospital for Sick Children, 555 University Avenue, Toronto, Ontario, M5G 1X8, Canado. (1661)

# UNIVERSITY OF TEXAS MARINE SCIENCE INSTITUTE

MARINE SCIENCE INSTITUTE

The University of Texas Marine Science Institute at Port Aransas is seeking applicants for an appointment, preferably at the ASSISTANT PROFESSOR level, from marine biologists capable of teaching courses in invertebrate zoology of marine organisms and of doing research in the area of physiological ecology. Applicants must have a strong research interest and a commitment to graduate training. Send curriculum vitae and a brief statement of research interests to the Director, The University of Texas Marine Science Institute, Port Aransas, Texas 78373. Affirmative Action/Equal Opportunity Employer. (1726)

#### UNIVERSITY OF GUELPH DEPARTMENT OF CHEMISTRY FACULTY POSITION

Applications are invited for a faculty position in the area of biochemistry or biophysical chemistry at the rank of assistant or associate professor, to begin September 1, 1975. Candidates must have a Ph.D. degree in chemistry or biochemistry and at least one year of postdoctoral experience in biochemistry or biophysical chemistry. Duties will include undergraduate and graduate teaching in biochemistry, supervision of graduate research, and independent research. Salary and rank will depend on qualifications and experience.

Applicants should provide a full curriculum vitae, transcripts of academic record, a brief description of research interests and a research proposal, and the names of three referees to A. K. Colter, Chairman, Department of Chemistry, University of Guelph, Guelph, Ontario, Canada, NIG 2WI. (1750)

# nature

A vacancy will arise soon in the Washington office of *Nature* for the important post of Assistant Editor responsible for supervising the refereeing of biological manuscripts submitted to the Washington office. A period of training in the London office under the supervision of the Biological Manuscripts Editor will precede the posting to Washington. The successful applicant may expect to be in Washington for not less than two years.

This job is an outstanding opportunity for a recently qualified British or American Ph.D who has a strong interest in ensuring the high quality of the biological papers we publish.

Apply with curriculum vitae and the names of two referees to:-

The Editor,
Nature,
Macmillan Journals Ltd.,
4 Little Essex Street,
London, WC2R 3LF

by November 15th

#### INSTITUTE OF GENETICS UNIVERSITY OF COLOGNE

#### POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral research assistantship sponsored by the Ger-man Research Association to study chromoman Research Association to study characteristics and expression of gene activity in cultured mammalian cells in collaboration with Dr. Klaus Willecke. The appointment is tenable for two years, commencing January 1, 1975. The salary will be about 5,000 per annum (salary of a married person, 27 years old). Applications consisting of a brief curriculum vitae and the names of two referees should be sent to Dr. Klaus Willecke, Institut für Genetik, D 5 Köln 41, (1753)Weyertal 121, West Germany,

#### UNIVERSITY OF VICTORIA DEPARTMENT OF BIOLOGY

Applications are invited for a continuing position to teach and organize the Department's introductory biology course. The appointment will be made at the Assistant Professor level, although applicants with exceptional experience and qualifications must hold a doctorate degree, have previous experience and a special interest in teaching introductory biology, and be active scholars in their field of research. The area of specialized research is of less consequence than the applicant's abilities as a teacher, although a field complementing the Department's specializations in marine science or field biology is desirable. Teaching duties commence in September, 1975, and the closing date for applications is December 31, 1974.

Applications should include a curriculum vitae

Applications should include a curriculum vitae and the names of three referees. Applications should be directed to Dr. Michael Ashwood-Smith, Chairman, Department of Biology, University of Victoria, Victoria, B.C., Canada, V8W 2Y2.

(1766)

### INSTITUTE OF TERRESTRIAL **ECOLOGY**

# ANIMAL **ECOLOGIST**

The Institute of Terrestrial Ecology requires an experienced ecologist to work on behavioural ecology of Vertebrates and, as a first task, to develop research on mammalan predators. He/she, will be a member of a group of ecologists based at Banchory, Kincardineshire, and be expected to provide expertise in behaviour studies and to guide other staff.

Candidates should have several years experience of research, preferably on vertebrate predators in more than one habitat, and a wide interest in the ecology of vertebrates and their prey, including birds as well as mammals.

#### **OUALIFICATIONS**

An appropriate first or second class honours degree (or equivalent) and at least four years relevant post-graduate experience.

Appointment will be to the Senior Scientific Officer/Principal Scientific Officer grade according to the age, qualifications and experience of the successful applicant.

# SALARY SCALES

S.S.O. £3,157 to £4,441 P.S.O. £4,227 to £5,550

Cost of living supplements are paid in addition to salary.

Non-contributory superannuation scheme.

Application forms and further particulars available from Establishments Division. Approach available from Establishments Division, Natural Environment Research Council, Alhambra House, 27/33 Charing Cross Road, London WC2H 0AX. Please quote reference

Closing date: November 29, 1974.

#### THE HORMEL INSTITUTE OF THE UNIVERSITY OF MINNESOTA

invites applications from qualied individuals for the position of

#### EXECUTIVE DIRECTOR

of the Hormel Institute which is located in Austin, Minnesota. The Executive Director is responsible for overall administration of an institute with 80-90 employees, including 20 of whom have academic rank. Candidates for this position should be recognized authorities in the lipid field, and should have at least 12 years of research experience in the field. The director is expected to maintain an active research program. Closing date for receipt of all materials is February 1, 1975. Send Curriculum vitae, a list of publications and names of three referees to Dr. J. E. Gander (Chairman, Search Committee), Department of Biochemistry, University of Minnesota, St. Paul, MN 55108. (1757)

#### ROYAL COLLEGE OF SURGEONS

Vacancies exist for two technicians in the Pathology Department. Histological experience is necessary for the first; microbiological experience would be an advantage in the second. Starting salary £1,986 p.a. plus Threshold on Whitley scale. Three year tenure.

Please apply Personnel Officer, Institute of Basic Medical Sciences, Royal College of Surgeons of England, 35-43 Lincoln's Inn Fields, London WC2A 3PN, Tel: 01-405 3474. (1759)

# UNIVERSITY OF GUELPH CHAIRMAN OF THE DEPARTMENT OF HUMAN KINETICS

DIRECTOR OF THE SCHOOL OF\*
PHYSICAL EDUCATION

PHYSICAL EDUCATION

Applications are invited for the combined position of Chairman of the Department of Human Kinetics and Director of the School of Physical Education, the appointment to be effective from July 1, 1975, when the present Director will complete his account term of office, or as soon as possible thereafter. The Chairman of the Department of Human Kinetics acts as the Director of the School of Physical Education, as well as administering the affairs of the Department of Athletics through its Director. The Department of Human Kinetics will be entering into the training of graduate students in 1975 as well as carrying a well established undergraduate programme. The position requires a recognized scholar with broad knowledge of human movement. Experience in university teaching is desirable.

movementa. Experience is desirable.

The term of office is three to five years, with a possible extension upon review.

Enquiries and applications, which will be treated in confidence, should be addressed to The Secretary, Selection Committee, Dean's Office, College of Biological Science, University of Guelph, Guelph, Ontario, Canada, NIC 2001 sity of Guelph, Guelph, Ontario, Canada, NIG 2W1.
Closing date for applications is January 1, 1975.

(1765)

# RESEARCH Marine Biology

Southampton Salary c. £4000 - £6000 p.a.

As part of the Board's Biological Research Programme the CENTRAL ELECTRICITY REŠEARCH LABORATORIES maintain a Marine Biological Unit at Fawley on Southampton Water. A biologist is now sought to lead this group, which includes biologists and chemists, in a study of marine and estuarial ecology in relation to electricity generation. The Laboratory is well equipped with experimental and analytical facilities and the successful applicant will have considerable scope for defining the programme. Publication of results is encouraged.

If you are a biologist with a record of scientific achievement and experience in a relevant field we would be interested to hear from you.

Write NOW to the Personnel Officer (Research),  $Central\ Electricity\ Generating\ Board,\ 15\ Newgate$ Street, London EC1A 7AU, quoting Ref. N/354.

> CENTRAL ELECTRICITY RESEARCH LABORATORIES

#### McGILL UNIVERSITY, DEPARTMENT OF BIOLOGY

HUMAN or MAMMALIAN CELL GENETICIST NEUROBIOLOGIST

TERRESTRIAL PLANT ECOLOGIST competent to develop a course in Canadian Flora

VERTEBRATE ETHOLOGIST

Four Assistant Professors will be hired in 1975 to join the regular academic staff in the Biology Department (currently approximately 50 members). Expertise is required in one of the four fields indicated above. The Department has major and honours programmes and groups of staff members conducting research in these four areas. All staff are expected to establish their own research programmes and to take an active part in teaching undergraduate and graduate students.

Applicants should send a curriculum vitae and the names of suitable referees before January 31, 1975 to Ms E. Mader, Administrative Assistant, Department of Biology, McGill University, P.O. Box 6070, Station A, Montreal, Quebec, Canada H3C 3GI. (1813)

# Overseas Development

# Lesotho Agricultural College

# Senior Lecturer— Farm Machinery and Estate Crafts

To plan syllabuses and implement teaching in Farm Machinery, Farm Carpentry, and Welding; plan and supervise workshop equipment; supervise demonstrators in farming crafts; plan and execute programme of practical tests in farming crafts. Applicants should have proven ability in the prescribed duties of the post,

# Farm Director and Senior Lecturer— Farm Management

To plan, direct and manage the College Farm; to draw up long-term management plans for the Farm in the context of the country's agricultural industry for the present and future; design and implement courses in farm management; lecture in elementary farm accounting; records and marketing. Applicants should have a degree or appropriate qualification and be experienced in the prescribed duties of the post.

# Senior Lecturer—Animal Husbandry

To assist in planning and management of livestock enterprises; to teach theory and practical skills with special emphasis on dairy and beef cattle; plan short courses and conferences for the Ministry of Agriculture field staff. Applicants should have a degree or diploma in agriculture and be experienced in the prescribed duties

# Senior Lecturer—Crop Husbandry

Assist in planning and management of grassland and cropping policy; teach theory and practice in these subjects; liaise with the Farm Machinery Lecturer in applica-tion of mechanisation to crop and grassland production; plan short courses for Ministry of Agriculture field staff. Applicants should have a degree or diploma in agriculture and be experienced in the prescribed duties of the post.

Terms (all posts): Salary will be in excess of current U.K. earnings plus a variable tax-free overseas allowance. Appointments for 2 years. Other benefits include free family passages, paid leave, children's education allowances, and free accommodation and medical attention. Superannuation rights may be safeguarded and all emoluments are paid by the British Government. Applicants should normally be citizent of and permantily resident in the United Kingdom. be citizens of, and permanently resident in, the United Kingdom.

For full details and an application form please apply, indicating post concerned, and giving details of age, qualifications and experience to:-

Appointments Officer

Ministry of Overseas Development

Eland House Stag Place London SWIE 5DH

(1845)

#### THE FACULTY OF MEDICINE OF MEMORIAL UNIVERSITY OF NEWFOUNDLAND

will appoint an Endocrinologist to its Basic Sciences Division in 1975. Individuals with research in-terests in metabolic regulation, neuroendocrinology or membrane studies will be considered.

Interested applicants should send resumé and names of three referees to:

Dr. Bruce H. Sells
Laboratories of Molecular Biology
Faculty of Medicine
Memorial University of Newfoundland
St. John's, Newfoundland
Canada

Before December 15, 1974.

(1755)

#### UNIVERSITY OF ALBERTA DEPARTMENT OF ZOOLOGY Edmonton, Alberta T6G 2E1, Canada

Edmonton, Alberta T6G 2E1, Canada
Two positions are available as Assistant or Associate Professor, from July 1, 1975. A specialist in some aspect of invertebrate zoology is needed to take major responsibility for teaching in a general course in invertebrates. A specialist in vertebrate morphology and vertebrate palaeontology; an interest in fishes is preferred. In both positions there will be opportunity for teaching at advanced levels. Strong research orientation and Ph.D., or equivalent, is required. Salary will be within the range Can \$13,440 to 23,416. Applicants send a curriculum vitae and the names of three referees to Dr. J. R. Nursall, Chairman, Department of Zoology, before January 31, 1975. (1756)

#### PENNSYLVANIA STATE UNIVERSITY

DEPARTMENT OF PHYSICS

Assistantships are available for graduate students wishing to pursue a Ph.D. program, starting September 3, 1975. Major research areas: Solid state and surface physics, field ion microscopy, low temperature physics, molecular spectroscopy, laser physics and nonlinear research, acoustics, particle and Q.E.D. theory. Half-time teaching assistantships carry a stipend of \$3.852 for nine months. Quartertime summer teaching appointments and some all-year research appointments are available. Address inquiries to Prof. R. H. Good, Jr., Head, 104 Davey Laboratory, University Park, Pa., USA 16802. (1770)

#### UNIVERSITY OF EAST ANGLIA SENIOR RESEARCH ASSOCIATE

SENIOR RESEARCH ASSOCIATE

Applications are invited from suitably qualified persons for a Senior Research Associateship in the Climatic Research Unit (associated with the School of Environmental Sciences). A good degree in meteorology, geophysics, or geography with acceptable qualifications in meteorology and geophysics, and previous experience of research and practical work on the large-scale circulation of the atmosphere or oceans, are desirable. This post is particularly concerned with a project for mapping the reported weather, and diagnosing the atmospheric circulation patterns prevailing, season by season, year by year, over the past thousand years. Salary on the lecturer scale, from £2.118 to £4.896, starting point determined by age and experience: the possibility exists of appointing a highly qualified person to points on the scale corresponding to a senior lectureship. The appointment will be for 3 years in the first instance, but may be extended for a further period. for a further period.

Applications (one copy only) with a curriculum vitae and list of publications, together with the names and addresses of two referees, to Establishment Officer, University of East Anglia, Norwich NR4 7TJ, England, by December 20, 1974, from whom further particulars may be obtained.

#### UNIVERSITY OF BIRMINGHAM TECHNICIAN GRADE 3

A Research Technician is required to assist in a Neurochemistry laboratory, in the Neurocommunications Research Unit. The work involved would mainly be biochemical with some physiological and animal experimentation. Some laboratory experience essential and preference will be given to applicants with a degree or O.N.C. in Chemistry or Richards subject. Biological subject.

Assistant Secretary, University of Birmingham, P.O. Box 363, Birmingham B15 2TT.

Ref. 581/C/579.

(1763)

#### DEPARTMENT OF ZOOLOGY UNIVERSITY OF CALIFORNIA, **DAVIS**

The Zoology Department has an opening either for an ecologist with research interests in aquatic organisms, or for a behaviorist working on causal mechanisms or genetics of vertebrate behavior. The person appointed will be expected to conduct research and to participate actively in undergraduate and graduate teaching. The appointment will be as an Assistant Professor—salary US \$12,800 to \$15,100. Persons who want to apply should send a curriculum vitae to: The Search Committee, Department of Zoology, University of California, Davis, California 95616, U.S.A.

The University is an Equal Opportunity and Affirmative Action employer. (1767)

#### ABSTRACTOR/TRANSLATOR

A recent graduate in microbiology or allied subject with a good knowledge of French required to prepare abstracts from French research literature in the fields of microbiology and biochemistry. The position is a full time one and part of the time will be spent at one or more of the large London libraries and part at I.R.L.'s offices. Please apply in writing to Dr. E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London WIV 5FG. (Quote Ref. T1). (1768)

#### UNIVERSITY OF LIVERPOOL DEPARTMENT OF BIOCHEMISTRY EXPERIMENTAL OFFICER

Applications are invited for the above post to work with a group on some aspects of Affinity Chromatography. Applicants should have research experience and a good honours degree in Chemistry or Biochemistry. The appointment will be made on the scale £1,953 to £2,757 per annum (plus threshold payments) and it is hoped that the successful applicant will take up the post as soon as possible. Application forms may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref RV/301,/N.

#### THE UNIVERSITY OF TEXAS CELL BIOLOGIST

Applications or noninations are invited for the position of Assistant Professor of Zoology. Duties include teaching in undergraduate and graduate courses and developing a strong research program in some area of cukaryote cell biology. Post doctoral research experience helpful. Applicants should submit curriculum vitae, reprints, a short statement of research and teaching plans and the names of three references to: Chairman, Department of Zoology, University of Texas at Austin, Austin, Texas, U.S.A. 78712. The University of Texas is an equal opportunity employer. (1771)

#### UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN

AT URBANA-CHAMPAIGN

COMPARATIVE PHYSIOLOGIST, Assistant or Associate Professor, for Fall 1975. Teaching includes comparative physiology of adaptation, metabolism and function of cells and organ systems. Postdoctoral research experience, publications essential. Apply: Dr. John S. Willis, Department of Physiology and Biophysics, University of Illinois, 524 Burrill Hall, Urbana, Illinois 61801. The University of Illinois at Urbana-Champaign is an Affirmative Action/Equal Opportunity Employer and encourages applications from members of minority groups and women. (1772)

#### ACADEMIC OPENING

ACADEMIC OPENING

The Department of Chemistry of Yale University is seeking applications for appointment to our faculty at the Assistant Professor level in inorganic chemistry. The appointment would become effective in the 1975-76 academic year. Expertise in x-ray crystallography is required; however, a research program in structural chemistry should complement a program in another subdiscipline, such as bioinorganic or organometallic chemistry.

Yale has an active Affirmative Action Program and we are especially interested in minority group or female candidates who meet the above criteria.

Candidates should request referees to write and should send a curriculum vitae, a list of publications, brief summaries of predoctoral and any postdoctoral research, and a brief outline of proposed research projects to the Chairman, Department of Chemistry, Yale University, New Haven, Connecticut, 06520. Applications should be sent promptly, preferably by December 31, 1974 to assure consideration.

**HEALTH DISTRICT (TEACHING)** Lambeth, Southwark and Lewisham Area Health Authority (Teaching)

# **Quality Controller**

Applications are infited from pharmacists or graduate chemists for the above post based at King's College Hospital.

The person appointed will be responsible for the management of the Laboratory and accountable to the Area Pharmacist. The work involves setting up procedures for routine analysis. Involvement in Research projects will be encouraged

Salary according to age, experience and qualifications within range £1,872 to £3,120 plus L.W. and Threshold agreements.

From January 1, 1975. £2,325 to £4,377 plus London Weighting. Application forms available from Personnel Department, King's College Hospital, Denmark Hill, London SE5 9RS. Tel: 01-274 6222 Ext. 2724/8

#### AUSTRALIA

MINISTRY FOR CONSERVATION, VICTORIA

# DIRECTOR OF NATIONAL PARKS

National Parks Service, Victoria

Applications are invited for the position of Director of National Parks from persons who have the following qualifications

- A sound knowledge of public or business administration together with broad experience and a proven record as an administrator in a field having a scientific or technical
- A degree in one of the natural sciences. A higher degree
- in the botanical or biological field will be preferred.

  Ability to lead and control staff trained in a variety of disciplines.
- Ability to communicate effectively with staff and with the community.

The Victorian National Parks Service presently controls 24 widely dispersed parks totalling 510,000 acres.

The Service is in a development stage in which new parks are being placed under its control and additional staff are being recruited to strengthen the existing establishment and to create and Interpretative Service Section.

Conditions of Employment-

Salary A \$18,375 per annum. Leave and other conditions equivalent to that applying to the Victorian Public Service. The position is statutory office but line of responsibility and duties may be varied in accordance with pending legislation and recommendations resulting from a Board of Inquiry into the Public Service.

Further particulars may be obtained from, and applications should be submitted to:

Minister for Conservation, 240 Victoria Parade, East Melbourne, 3002, Victoria, Australia.

Applications close on November 29, 1974.

(1830)

# Findyour place in British Gas

## .PHYSICIST

London Research Station carries out research and development work on a wide variety of problems associated with the Gas Industry; the work ranges in scale from pilot-plant chemical engineering and computer control of transmission and distribution networks to the detailed study of elementary chemical and physical processes.

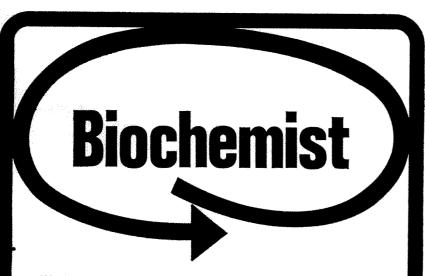

The Physics Division, within the Station, has a vacancy for a Scientist to be responsible for developing and applying a variety of physical measuring devices of potential use to the Gas Industry, e.g. flow measurement, laser, optical and spectroscopic techniques.

Applicants should have a scientific or engineering background to degree standard; experience in the use of any of the devices mentioned above would be an advantage.

Starting salary will depend on qualifications and experience, but will be at a point on scales rising to £3,834 or £4,197 plus Threshold payments.

For further details and an application form, please contact the Research Secretary, British Gas Corporation, London Research Station, Michael Road, Fulham, London, SW6 2AD, quoting reference 4010/14/NA.

**BRITISH GAS** 

We have a vacancy in our Pharmacology Department for a qualified biochemist with either H.N.C. or first degree, Ideally, candidates should have 1-3 years relevant experience but we would consider newly qualified applicants.

The work would involve radio-chemical and chemical analysis of biogenic amines associated with our current research programme in the C.N.S. area.

The laboratories are situated in an attractive 47 acres site and the fringe benefits include, non-contributory pension scheme, B.U.P.A., and four weeks holiday.

Please write giving details of experience to:

The Personnel Manager, Lilly Research Centre Ltd., Erl Wood Manor, WINDLESHAM, Surrey, or telephone for an application form Bagshot 73631. (1849)

# LY RESEARCH CENT

#### University of Bradford LECTURERS (2 Posts) IN THE SCHOOLS OF CIVIL AND STRUCTURAL ENGINEERING

Applications are invited for the above posts. For one post preference will be given to applicants with good re-inforced concrete design experience.

Salary within scale £2,118 to £4,896 p.a. Superannuable

Further particulars and application forms Further particulars and application forms (to be returned a.s.p.) obtainable from the Registrar, Posts CE/L/12 and 17, University of Bradford, Richmond Road, Bradford BD7 1DP, West Yorkshire, Informal enquiries to Professor C. B. Wilby. (1803)

#### M.R.C. CLINICAL RESEARCH CENTRE.

(Northwick Park Hospital), Watford Road, Harrow, Middlesex, HA1 3UJ.

Harrow, Middlesex, HA1 3UJ.

TECHNICIAN for work on the chemical study of some inborn errors of metabolism. The programme is particularly concerned with inherited metabolic diseases in which there appears to be a primary abnormality of organic acid metabolism and it would be suitable for a holder of H.N.C. in chemistry with experience in gas chromatography. Ref. 123D/2B/4222.

Salary within the range £1.986 to £2.961 plus Threshold increase.

Further details and application forms from Mrs J. Tucker-Bull. Please quote reference. (1775)

#### M.R.C. CLINICAL RESEARCH CENTRE,

(Northwick Park Hospital). Watford Road. Harrow, Middlesex, HA1 3UJ.

JUNIOR TECHNICAL OFFICER/TECHNICAL OFFICER to work in the Division of Psychiatry on biochemical and physiological investigations in psychiatric illness. Experience in neuropharmacological techniques an advantage. Candidates must hold H.N.C. or ordinary degree in relevant subject.

in relevant subject. Salary within the range £1,986 to £2,961 plus Threshold increase, depending upon qualifications and experience.

Ref. 125/2/A30.

Please apply to Mrs J. Tucker-Bull for application form and further details. (1776)

#### UNIVERSITY OF ABERDEEN SENIOR LECTURESHIP/ LECTURESHIP IN GEOLOGY AND MINERALOGY PETROLEUM EXPLORATION STUDIES

Applications are invited for the above posts (two vacancies). Preference will be given to candidates with special interests or experience in any of the following fields: Petroleum Geology, Well Logging, Formation Evaluation, Reservoir Studies, Salary on scale: Senior Lectureship £4,707 to £5,844 per annum. Lectureship £2,118 to £4,896 per annum with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (3 copies) should be lodged by December [4, 1974. (1764)

#### VICTORIA UNIVERSITY OF WELLINGTON NEW ZEALAND

#### SENIOR LECTURER OR LECTURER IN PHYSICAL CHEMISTRY

IN PHYSICAL CHEMISTRY

Applications are invited for the above-mentioned post; it is hoped that the successful applicant will have interests related to the fields of research at present being pursued in the Department, in particular transport properties, structure, reaction kinetics and electrochemistry of the liquid and solid states including mineral systems, especially pressure and temperature effects.

Salary range: Lecturer NZ\$7,361 to \$9,339 p.a. Senior Lecturer NZ\$9,503 to \$11,153 bar \$11,484 to \$12,142. The level of appointment and the initial salary wil be determined by the qualifications and experience of the appointee. An allowance is made towards travel and removal expenses.

Further particulars and application procedure available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H OPF.

Applications close November 30, 1974. (1779)

Applications close November 30, 1974, (1779)

#### UNIVERSITY OF BRISTOL DEPARTMENT OF SURGERY

Applications are invited for the post of RESEARCH ASSISTANT/ASSOCIATE

to collaborate in a study involving the adoptive transfer of immunity to patients with advanced malignant disease.

Candidates must posses a Ph.D.

The post is available for two years, in the first stance, from March 1, 1975, and carries a salary up to £2,412 per annum (plus F.S.S.U.) according to experience

Applications in writing with the names of two referees to Professor J. H. Peacock, Department of Surgery, Bristol Royal Infigurary, Bristol B28HW as soon as possible please. (1777)

#### THE ROYAL HORTICULTURAL SOCIETY

#### APPOINTMENT OF BOTANIST

Applications are invited for the post of Botanist at the Society's Garden at Wisley.

The duties will include advisory work on plant identification, and physiology, genetics and chemistry related to horticulture; demonstrations to trainees, cataloguing and labelling plants at Wisley and Committee work. Graduates in botany or horticulture preferred.

The salary, reviewed annually, will be related qualifications and experience. The post is pensionable.

Applications with details of qualifications and experience and the names of two persons to whom reference may be made should be sent so as to reach the Secretary, Royal Horticultural Society, Vincent Square, London SWIP 2PE, by Monday December 2, 1974. (1783)

#### UNIVERSITY OF BRISTOL DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited from candidates with re-Applications are invited from candidates with research experience in protein chemistry and/or enzymology for a Postdoctoral Research Assistantship to work in collaboration with Dr J. Williams on an M.R.C. supported project involving a structural and functional investigation of metal-binding fragments from transferrin.

The appointment is available now for a period of up to three years at an initial salary up to £2,412 (plus benefit of Threshold Agreement supplement as appropriate).

Interested candidates should write to: Dr J. Williams, Molecular Enzymology Laboratory, Department of Biochemistry, University of Bristol, Medical School, Bristol BSS 1TD. (1784)

#### UNIVERSITY OF BRISTOL DEPARTMENT OF BOTANY **TECHNICIAN GRADE 5**

There is a vacancy for an Electron Microscopist Grade 5 in the Department of Botany. The person appointed would have to accept overall responsibility for the operation, full maintenance and servicing of three microscopes A.E.I. E.M. 6G. A.E.I. E.M. 6B. and Cambridge Instrument Stereoscan S.4. together with ancillary equipment. Familiarisation courses could be arranged for otherwise suitable candidate. Salary £2,007 per annum on scale to £2,382 per annum. Threshold supplements are also payable under current arrangements. (Salary scale under review). (Salary scale under review).

(Salary scale under review).

Applications, giving full details of qualifications and experience, together with names of two referees, should be sent to the Laboratory Superintendent, Department of Botany, University of Bristol, Woodland Road, Bristol BSS 1UG. (1785)

#### MEMORIAL UNIVERSITY OF NEWFOUNDLAND **CANADA**

DEPARTMENT OF BIOLOGY Applications are invited for the position of BACTERIAL SYSTEMATIST

BACIERIAL SISIEMAINI

The successful candidate must also have a good background in either Bacterial Physiology or Immunology. A background in Bacterial Genetics would also be desirable. Appointment will be made at the Assistant Professor level, to commence September 1, 1975. Applicants should have a strong interest in undergraduate teaching and be capable of initiating an independent research programme.

Closing date for receipt of applications: March 15, 1975. Apply to Professor J. Phipps, Head. Department of Biology, Memorial University of Newfoundland, St. John's, Newfoundland, Canada. (1788)

# **AUSTRALIA** THE AUSTRALIAN MUSEUM, SYDNEY, NEW SOUTH WALES

# **CURATOR/ASSISTANT CURATOR**

(two positions)

The Australian Museum is located in Sydney and has a total staff of over 140 with 12 departments covering all systematic groups of animals plus Environmental Studies, Palaeontology, Mineralogy and Anthropology. The scientific staff numbers 30. Field research is emphasised and a wide range of field equipment is available. Applications are invited for the above positions.

Salary:

Assistant Curator \$A7,287 to \$A11,322 per annum; Curator \$A11,862 to \$A12,619 per annum; with progression to \$A13,526 per annum subject to certain condition.

# **CURATOR/ASSISTANT CURATOR**

#### DEPARTMENT OF MOLLUSCS

Qualifications:

Essential: Degree with major in Zoology.

Desirable: Postgeaduate qualifications with research in Zoology. Preference will be given to candidates with experience in terrestrial and/or fresh water molfuscan taxonomy and biology. Previous experience in management of museum collection will be an advantage.

**Duties:** 

Research on taxonomy/biology of Mollusca; curation of collections of Mollusca; answering public and professional scientific enquiries.

# **CURATOR/ASSISTANT CURATOR**

### **DEPARTMENT OF ENVIRONMENTAL STUDIES**

**Oualifications:** 

Essential: A degree in some aspect of Marine Ecology, demonstrated ability to initiate and conduct research.

Desirable: Experience in planning and supervision of team research. Preference will be given to an applicant with research interests in estuarine ecology and man/environment problems.

**Duties:** 

Initiate and conduct ecological research and environmental surveys in the marine environment; answer public and professional scientific enquiries relating to marine ecology and human impact on the marine environment. Subject to certain conditions the successful applicants will be eligible for:-

Payment of fares to Sydney;

Financial assistance towards cost of removal expenses;

Financial assistance towards initial accommodation expenses.

For further information and application form telephone or write to the Recruitment Section, New South Wales Government Offices, 66 Strand, London WC2N 5LZ (Tel: 01-839 6651 Extension 194), where applications close on MONDAY, DECEMBER 2, 1974. When telephoning or writing, please quote reference 44/576 (N).

#### DIRECTOR

Applications are invited for the position of DIREKTOR DES INSTITUTS FÜR TIERZUCHT UND TIERVERHALTEN FORSCHUNGSANSTALT FÜR LANDWIRTSCHAFT,

a federal research institution engaged in reproductive biology, animal behaviour and genetics. Staff of 250 including 16 scientists. Research budgeted Facilities: 2,500 m² of laboratory space; 4 research farms (1200 ha): live stock of 1,200 cattle. 2,000 pigs. 1,000 sheep. Locations: main laboratories and 2 farms at Mariensee near Hannover; laboratory and 2 farms at Trenthorst near Lübeck.

Qualifications: Internationally established research reputation. Applicants with biochemical and physiological background should be enabled to coordinate the research programmes of the different

coordinate the research programmes of the different

sections.
Salary: approx. 65,000 DM/annum (B 3 tenure position in government service).

position in government service).

To apply, send curriculum vitae, summary of research activities, list of publications and reprints before December 31, 1975 to:

Prof. Dr E. Zimmer
Präsident of
Forschungsanstalt für Landwirtschaft
Bundesallee 50
D 33 Braunschweig
Federal Republic of Germany

(1792)

(1792)

# **Pharmacist**

required for research and developlaboratories. Applicants must have experience in research, development and testing of new pharmacoutical dosage forms. Salary commensurate with age and experience. Application forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (1801)

# LECTURER IN **HUMAN PHYSIOLOGY**

Applications are invited for the above post in the Department of Biological Sciences from those holding an Honours degree in an appropriate discipline. Preference will be given to candidates with a higher degree and with experience in advanced teaching and research. The duties of the post will be largely associated with a recently established Honours degree course in Applied Biology.

Salary Scale: Up to £4,017 per annum depending upon experience, plus £123 per annum for approved teacher training. Application forms and further particulars may be obtained

> The Director, Glasgow College of Technology, North Hanover Place. Glasgow G4 0BA,

and should be returned within ten days of the appearance of this advertisement (1835)

#### NORTH LONDON **BLOOD TRANSFUSION CENTRE** TISSUE TYPING

Technician/Scientific Officer required to assist in antibody screening and reagent preparations. Previous experience in this field would be advantageous but is not essential.

#### MICROBIOLOGY

Scientific Officer required to work on development of techniques for detection and assay of Tetanus antibody in human sera. Experience in serology or biochemistry desirable.

#### **BLOOD GROUP SEROLOGY**

Scientific Officer required for quality control section. Experience in blood group serology essential and automated techniques desirable.

Salaries and conditions are those of the appropriate Whitley Council. Applications and enquiries to the Director. Deansbrook Road, Edgware, Middx. HA8 9BD.

iddx. HA8 9BD. Closing date 2 weeks after the date of insert. (1786)

# university of wales universit

#### RESEARCH ASSISTANT

Applications are invited for the vacancy of Research Assistant in the Department of Genetics to work on assay of genetic damage by heavy metals in marine organisms. Applicants should be graduates in a biological subject with research experience preferably in genetics or cytogenetics.

The appointment, which will commence as soon as possible, will be for one year in the first instance, and will be in the range £1,953 to £2,058 per annum.

Further particulars and application forms may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea SA2 8PP to whom they should be returned by Tuesday, November 19, 1974.

DEPARTMENT OF GEOLOGY

#### UNIVERSITY OF WINDSOR RESEARCH ASSOCIATE

required to fill a permanent position. Applicants should have a Ph.D. or M.Sc. in geoscience. Research studies will be major and minor element geochemistry and/or into the physical properties of rocks and glacial deposists. Teaching duies will be minor. Salary will be commensurate with qualifications. Send résumé with names of three potential referees to:

Dr D. T. A. Symons
Department of Geology
University of Windsor
Windsor, Ontario, Canada N9B 3P4

(1791)

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN CLINICAL PHYSIOLOGY, tenable as soon as possible. Applicants should possess a medical qualification and relevant postgraduate training. Duties include lecturing in basic and clinical Physiology and demonstrating in experimental human and animal physiology to students working for the medical degree.

PURDUE UNIVERSITY

Postdoctoral Research determining the structures of polynucleotides and polysaccharides mainly by X-ray fiber diffraction analyses wanted for 1-3 years. Send curriculum vitae with names of two referees to:

Professor Struther Arnott Department of Biological Sciences Purdue University West Lafayette, Indiana 47907

#### UNIVERSITY OF THE WEST INDIES **JAMAICA**

degree.

Salary scales: (a) J\$10,992 to J\$14,472, (b) J\$7.860 to J\$10,752 p.a. (£1 sterling=J\$2.12) Additional renumeration will be available for all clinical duties. F.S.S.U. Unfurnished accommodation for a maximum of three years at 10% of salary. Therafter 20% of salary payable in lieu of housing. Family passages; triennial study leave. Detailed applications (3 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Detailed particulars are available and should be obtained from the same source before an application is made. (1787)

#### NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the post of

#### TIMBER RESEARCH OFFICER

Applicants must have a degree or equivalent pro-fessional qualification in timber or structural engineering and experience in the use of timber in the mining and other industries.

The timber research officer's duties will include making surveys of timber and forest products utilization by the Zambian industries including the mining industry, planning and executing applied research in the use of timber and forest products and liaising with industries on timber and forest products utilization.

Salary according to qualifications and experience on the scales:— Senior Professional Officer K4,680 by 240 to K5,640

Principal Professional Officer
K5,840 by 240 to K6,800
Senior Principal Professional Officer
K7,000 by 200 to K7,600

K7,000 by 200 to K7,600

There is a superannuation scheme for Zambians. Non-Zambians will be paid a graduated gratuity of 20% of the total earnings in the first year. 25% in the second year and 30% in the third year of resident service. Passages will be paid for the officer, wife and minor dependent children.

Applications giving full personal details, qualifications, experience and naming three referees should be submitted to:

The Secretary General,
National Council for Scientific Research,
P.O. Box CH 158,
Chelston, Lusaka,
Zambia. (1794)

#### IMPERIAL COLLEGE NON-STOICHIOMETRIC OXIDE ELECTRODES

Applications are invited for a three year postdoctoral research assistantship. The project is principally concerned with the characterisation of nonstoichiometric oxides using high resolution electron
microscopy, and subsequent correlation of the defect
structure with electromechanical behaviour. Excellent
facilities are also available for the examination of
oxide materials in the 1 mev electron microscope.
Starting salary in the range £2.118 to £2.412 plus
London allowance, threshold payments, and
F.S.S.U. benefits. Applications should be made to
Dr B. C. H. Steele, Department of Metallurgy and
Materials Science, Imperial College, London
SW7 2BP.

#### STAFFORDSHIRE AREA HEALTH AUTHORITY SOUTH EAST STAFFORDSHIRE HEALTH DISTRICT THE GENERAL HOSPITAL

BIOCHEMIST (Basic Grade)

required to work under the Principal Biochemist in well equipped laboratory at the above hospital.

Single accommodation may be available.

Further information from the Principal Biochemist, The General Hospital, Burton-on-Trent. Applications stating experience and naming two referees to Personnel Officer, Burton District Hospital Centre, Belvedere Road, Burton-on-Trent DE13 0RB. (1799)

#### COMMONWEALTH AGRICULTURAL **BUREAUX**

VACANCY FOR

SCIENTIFIC INFORMATION OFFICER AT THE

#### COMMONWEALTH FORESTRY **BUREAU**

COMMONWEALTH FORESTRY INSTITUTE. SOUTH PARKS ROAD, OXFORD OX1 3RD

**Duties:** Abstracting and indexing of technical papers and dealing with enquiries.

Qualifications: Applicants should have a reading knowledge of some foreign language(s), and should be graduates in forestry or biology, or linguists with an interest in biology. Opportunities for further training.

training.

Salary: In scale £1,592 to £2,996 (bar), £3,157 to £3,943 (bar), £4,275 to £4,505, plus a compensatory allowance (taxable but not superannuable) of 4½% to offset personal contribution to F.S.S.U., and threshold payments to date. Starting salary, according to qualifications, age and experience, will be in the lower sector of the scale.

Application forms and full particulars from the

Application forms and full particulars from the Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN. Closing date for applications: November 30.

(1791)

(1789)

#### TWO VISITING INSTRUCTORS OR ASSISTANT PROFESSORS OF BIOLOGY

ASSISTMENT PROFESSORS OF BIOLOGY
to be appointed for two years each. Teaching duties
include: Introductory Biology and two of the following—Embryology, Cell Physiology, Vertebrate Histology and General Ecology, Interested person
should send curriculum vitae, transcripts and three
letters of reference by January 10, 1975 to: Chairman Search Committee, Biology Department, Kenyon College, Gambier, Ohio 43022.

Kenyon College is an equal-opportunity employer
(1802)

#### UNIVERSITY OF MELBOURNE CHAIR OF PSYCHOLOGY

CHAIR OF PSYCHOLOGY

Applications are invited for the Chair of Psychology which has become vacant following the resignation of Professor A. Heron, It is hoped that the successful applicant will take up duties on August 1, 1975 or as soon as possible thereafter.

Salary: \$A19,614 per annum (under review). Further information, including details of application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment, is available from the Association of Commonwealth Universities (Appts). 36 Gordon Square, London WC1H 0PF.

Applications close on January 10, 1975.

(1806)

#### MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF BOTANY SENIOR TUTOR

SENIOR TUTOR

Applications are invited for the post of Senior Tutor in the Department of Botany, from those with research interests in any area of the subject. Candidates will be expected to have gained a Ph.D. or have equivalent experience. The successful applicant will be expected to earry out research in the field of his specialty, to help with the planning and running of first-year laboratory classes, and to do some lecturing and demonstrating in later years.

Salary Range: \$A7,545 to \$A9,002 per annum with superannuation based on an endowment assurance scheme, the employee and employer contributing 5% and 10% respectively.

Benefits: Travelling expenses for appointee and family; removal allowance; temporary housing for an initial period, repatriation after three years service if desired.

Further general information and details of application procedure are available from the Academic Registrar, Monash University, Wellington Road. Clayton, Victoria 3168, Australia or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH 0PF. Enquiries about the Department to the Chairman, Professor M. J. Canny, in the University, Applicants should quote reference No. 43013.

Closing Date: November 25, 1974.

The University reserves the right to make no appointment or to appoint by invitation.

#### ROYAL POSTGRADUATE MEDICAL SCHOOL POSTDOCTORAL BIOCHEMIST

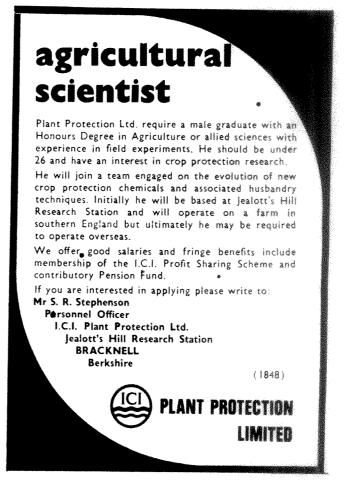

required to study the enzymology of carboxylases both from animal tissues and children with inborn errors of metabolism affecting mitochondrial carboxylases. This position is available for 1 year in the first instance with the possibility of extension for a further two years. Starting salary up to £2.511 per annum according to experience.

Applications including full curriculum vitae to the Personnel Officer, R.P.M.S. Hammersmith Hospital, Du Cane Road, London W12 0HS, quoting Ref. No. 2/474N. ((1812)

#### UNIVERSITY OF MANCHESTER SENIOR LECTURER IN EXPERIMENTAL PATHOLOGY

EXPERIMENTAL PATHOLOGY

Applications are invited for this post in the Department of Pathology. The post involves teaching the principles of Pathology and insearch within a group investigating the immunological and migratory properties of lymphocytes. This group which is partly supported by an M.R.C. programme is concerned with the recognition structures on lymphocytes and endothelial cells which govern the migration of lymphocytes from the blood into the tissues. For this project experience of membrane fractionation techniques or glycoprotein chemistry would be relevant. A second project is concerned with the recognition of transplantation and other antigens by T cells. The post will not carry clinical duties. Salary range p.a.: £4,707 to £5,844. F.S.S.U. Further particulars and application forms (returnable by December 21) from the Registrar, The University, Manchester M13 9PL. Quote Ref. 229/74/N. (1809)

#### WANTED

A postdoc in population biology interested in genetic structure of populations and species to con-duct research 1975-6, on a grant basis. Send information, curriculum vitae, references

and reprints to:
Prof. Eviatar Nevo.
Department of Biology,
University of Haifa,
Israel.

(1800)

#### UNIVERSITY OF OXFORD DEPARTMENT OF BIOCHEMISTRY

A Postdoctoral Research Assistant is required for work on the structures, kinetics and mechanisms of pyridine-nucleotide linked dehydrogenases, financed by the S.R.C. and beginning as soon as possible. The appointment will be for one year in the first instance, at a starting salary of not less than £2,010 p.a., plus threshold payment (at present £166 p.a.), with a possibility of further extension.

extension.

Applications, including curriculum vitae and the names of two referees, should be sent to:
Dr K. Dalziel,
Department of Biochemistry,
University of Oxford,
South Parks Road,
Oxford OX1 3QU.

(1816)

### THE POLYTECHNIC WOLVERHAMPTON

WELLCOME TRUST RESEARCH ASSISTANT

Applications are invited for a research assistant to participate in a project (supported by the Wellcome Trust) to investigate the function of intestinal peroxisomes with special reference to a role in lipid and cholesterol metabolism. The project will be supervised by Dr. M. Connock and the post is for three years. Applicants should hold, or be about to receive, a Ph.D. in Biochemistry, Physiology or related subject.

Commencing salary is up to £2,223 per annum. Further details can be obtained from The Establishment Officer, The Polytechnic, Wolverhampton WV1 1LY.

#### LIVERPOOL SCHOOL OF TROPICAL MEDICINE

DEPARTMENT OF PARASITOLOGY

DEPARTMENT OF PARASTOLOGY

A LECTURER/SENIOR LECTURER (Technical Assistance) is required in this Department, Applications are invited from candidates holding a medical qualification registrable in the U.K. of a good science degree and doctorate in relevant subjects. Practical experience in the parasitology of tropical diseases is essential and preference will be given to candidates who already have experience in teaching and/or research on parastic diseases in the developing countries.

The successful applicant will be required to spend periods of service overseas at teaching and/or research centres but will be based in this Department.

ment.
Salary will be within the University scale for Lecturer/Senior Lecturer and the starting point will be commensurate with qualifications and experience. The appointee will be entitled to participate in the University Pension Scheme, Further information may be obtained from the understance.

Further information may be obtained from the undersigned.

Applications together with the names of three referees should be sent to the Dean, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool L3 5QA, to arrive not later than December 15, 1974. Overseas candidates should apply by airmail.

PHARMACOLOGIST, experienced, medical or veterinary qualifications preferred. required for pharmacological research and toxicological studies of compounds of potential therapeutic importance. Excellent apportunities for advancement in modern. well-equipped laboratory, Pension Assurance Scheme. Application forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London (1814)

#### UNIVERSITY OF STRATHCLYDE DEPARTMENT OF PURE & APPLIED CHEMISTRY

**TECHNICIAN GRADE 3** 

A vacancy exists for an experienced Technician qualified to at least O.N.C. in Chemistry, or a graduate, to assist with a project in Organometallic Chemistry.

This post is for a period of three years.

Salary Scale: £1,650 to £1,920 plus threshold payment

payment

Applications in writing, quoting reference C.81, should be made to The Personnel Officer, University of Strathclyde, Royal College Building, 20 George Street, Glasgow G1 1XW. (1819)

#### UNIVERSITY OF WARWICK RESEARCH TECHNICIAN

The Department of Biological Sciences has a vacancy in the microbiology research laboratories for a Research Technician. Applications are invited from persons with experience of biochemical and/or microbiological techniques. The post is for a fixed contract period terminating on September 30, 1975. Salary on the Technician Grade 3 scale £1,650 by £54 to £1,920 p.a. plus threshold payments.

Applications in writing quoting Ref. No: 13/D/74 to the Academic Registrar, University of Warwick, Coventry CV4 7AL by November 18, 1974.

#### LONDON SCHOOL OF HYGIENE AND TROPICAL **MEDICINE**

(University of London) Keppel Street, WC1E 7HT

ROSS INSTITUTE OF TROPICAL HYGIENE SENIOR LABORATORY

# **TECHNICIAN**

Applications are invited from suitably qualified and widely experienced persons in medical laboratory subjects for a post as Senior Technician in the Department. Present research work includes immunofluorescent diagnosis, parasitology, insect genetics and experimental pathology: an interest in tropical medicine an advantage. Candidates should hold H.N.C./F.I.M.L.T. or be graduates in a relevant discipline. Salary, depending on age, qualifications and experience up to £3,573 plus £126 London Weighting and threshold payments. Possibilities of promotion to higher grades. Pensionable post; interest-free season ticket scheme. Applications in writing, giving full career details and naming two referees, to Secretary (AI) by December 16, 1974. Preliminary inquiries to Professor D. Bradley (01-636 8638 ext. 210).

#### TWO TECHNICIANS (Qualfied)

required for research in the Department of Medicine. One post involves the use of immunological and tissue-culture techniques, the other the use of radioimmunoassays. Previous experience preferable but not essential. Apply in writing, stating age and giving details of education, qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SEI 9RT, quoting Ref. D.M. (1824)

#### **BIOCHEMIST**

Investigation field: Calcium metabolism. Metabolism of P.T.H. and Calcitonin. Immunradiometric assays for different hormone species available. Radioreceptor assay for human P.T.H. Optimal financial and research conditions. Dr. R. D. Hesch, 34 Goettingen, Med. Univ. Klinik, Endocrinology, Germany. (1829)

#### UNIVERSITY OF EDINBURGH DEPARTMENT OF BOTANY RESEARCH ASSOCIATE IN PLANT TAXONOMY

Applications are invited from Honours graduates with postgraduate experience for the post of Research Associate financed by the Science Research Council to collaborate in writing the Flora of Turkey.

The salary range is £2,118 to £2,757 per annum, with F.S.S.U., depending on qualifications and taxonomic experience.

Further details may be obtained from Dr. P. H. Davis, Department of Botany, Royal Botanic Garden, Edinburgh EH3 5LR. The closing date for applications is November 23, 1974. Please quote reference 5053. (1815)

The Department of Physics at the Instituto Venezolano de Investigaciones Científicas (I.V.I.C.) has openings for experimental physicists with strong research curriculum in neutron physics, low temperature physics, quantum optics or magnetic resonance (E.S.R. and N.M.R.). Participation in graduate teaching is also desired. Preference will be given to Spanish speaking applicants. The positions can become permanent after one year. The salaries depend on experience but are typically around \$1,500.—Applications (including recommendations) should be submitted to: George Bemski, Centro de Fisica, Instituto Venezolano de Investigaciones Científicas, Apartado 1827. Caracas 101. Venezuela. (1826)

#### SEALE-HAYNE COLLEGE LECTURER IN THE DEPARTMENT OF PHYSICAL SCIENCES

Applications are invited from suitably qualified AGRICULTURISTS OR CHEMISTS. Candidates should have interests in one or more of the following:—

# ANIMAL NUTRITION SOIL SCIENCE FOOD SCIENCE

The main courses taught at the College include five Higher National Diplomas, two Ordinary National Diplomas as well as post-graduate/post-diploma certificate courses.

The appointment will be at either the Lecturer Grade I or Lecturer Grade II, Scales of Salaries for Teachers in Further Education, according to age and experience. Further particulars may be obtained from The Principal, Seale-Hayne College, Newton Abbot, Devon, to whom applications should be sent as soon as possible.

#### UNIVERSITY OF VICTORIA DEPARTMENT OF CHEMISTRY FACULTY POSITION IN INORGANIC CHEMISTRY

Applications are invited for a faculty position (professor or senior associate) in Inorganic Chemistry to commence July 1, 1975. Applications will also be considered from outstanding candidates at a more junior level.

The appointee will be expected to participate fully in departmental undergraduate and graduate teaching and in research.

Applicants should submit their curriculum vitae, including biographical information, a list of publications, and a statement of research interests and should arrange at the time of application for three letters of recommendation to be forwarded

Dr. A. D. Kirk, Chairman, Department of Chemistry, University of Victoria, Victoria, B.C., Canada V8W 2Y2.

(1827)

#### IMPERIAL COLLEGE UNIVERSITY OF LONDON LECTURESHIP IN PETROLEUM GEOLOGY

Applications are invited for a lectureship in the department of geology under the direction of Professor W. D. Gill.

Requirements are a good degree and practical experience in the petroleum industry.

Salary depending on qualifications and experience in the scale £2,118 to £4,896 plus £213 London allowance. Superannuation under F.S.S.U. scheme, Applications with curriculum vitae and names of two referees to:

two referees to:

Professor W. D. Gill,

Department of Geology,

Imperial College of Science and Technology,

London, SW7 28P.

Closing date November 30, 1974. (1.

#### DEPARTMENTAL ASSISTANTS

DEPARTMENTAL ASSISTANTS

One or two vacancies for organic chemists of postdoctoral status. Appointment: 2 years, extension to 3 possible. Duties: collaboration with one of the research groups (for one appointment preference will be given to candidates interested in peptide synthesis) and supervision of undergraduate experiments. Salary: from £2,118 plus threshold supplements and superannuation (at present F.S.U. but it is likely that other arrangements will be introduced before October 1975). A successful candidate would be allowed to undertake some college teaching in addition.

Starting date: October 1, 1975. Applications with the names of two referees to the Administrator, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY as soon as possible before January 31.

### UNIVERSITY OF **CAMBRIDGE**

DEPARTMENT OF ZOOLOGY

A technician is urgently required to assist in the Biological Microprobe Laboratory, which is concerned with the X-ray microanalysis of ions and electrolytes in frozen hydrated biological tissues.

O.N.C./H.N.C. or equivalent qualification required with 3 to 4 years' experience. Some training and an interest in electronics is essential, and general workshop and laboratory experience would be an advantage. Training and experience in biology and transmission electron microscopy is not required.

transmission electron microscopy is not required.

The salary range is £1,650 to £1,920 plus threshold payments.

Applications and enquiries should be addressed to The Secretary, Department of Zoology, Downing Street, Cambridge CB2 3EJ, (Cambridge 58717).

Closing date: November 30, 1974.

(1818)

#### FLINDERS UNIVERSITY OF SOUTH AUSTRALIA

SCHOOL OF MEDICINE

#### SENIOR LECTURER/LECTURER IN CLINICAL PHARMACOLOGY

Applications are invited for a Senior Lecture-ship/Lectureship in Clinical Pharmacology in the new School of Medicine.

new School of Medicine.

The School of Medicine will form an integral part of the Flinders Medical Centre, a 700-bed teaching hospital located on campus at Bedford Park, Adelaide. The first medical students began in 1974 and it is hoped that the appointee will take up his position by mid-1975 in order to participate in the teaching of pharmacology in the early years of the integrated curiculum.

A suitable position propositor will have re-

A suitably qualified appointee will have responsibility in the areas of teaching, research and clinical service. Lecturers with medical qualifications registrable in South Australia receive a clinical loading, the amount depending on their qualifications and the degree of clinical responsibility undertaken.

Conditions of service include provision for transportation expenses, superannuation, tenure, study and long service leave.

Present salary scales are Lecturer—\$A9,002 to \$A12,352; Senior Lecturer—\$A12,643 to \$A14,724. Superannution is on the F.S.S.U. basis.
Further information may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH 0PF.

Applications should be lodged with the Registrar, The Flinders University of South Australia, Bedford Park, South Australia 5042, in duplicate, by November 29, 1974.

#### UNIVERSITY OF EXETER DEPARTMENT OF PHYSICS

#### POSTDOCTORAL RESEARCH **ASSISTANTSHIP**

Applications are invited for a Postdoctoral Research Assistantship in Theoretical Physics supported by the Science Research Council. The research work will involve the use of N-body Faddeev methods to study molecular rearrangement processes at thermal energies; the techniques to be used could be of interest to applicants with experience in either Atomic, Molecular, High-Energy or Nuclear Physics.

Atomic, Molecular, High-Energy or Nuclear Physics.
The appointment is for two years (initial salary £2,118 plus threshold payments plus superannuation benefits) at a starting date to be agreed but preferably not later than April 1, 1975.
Informal enquiries may be addressed to Dr. T. W. Preist, Department of Physics, University of Exeter, Stocker Road, Exeter EX4 4QL, (Tel. No: Exeter 77911, Ext. 452).
Candidates should forward four copies (overseas candidates 1 copy) of their application giving details of their qualifications and experience together with the names and addresses of two referees to The Secretary of the University, Northcote House, The Queen's Drive, Exeter EX4 4QJ not later than December 2, 1974. Please quote reference 12/2/7079 in all correspondence.

#### UNIVERSITY OF SYDNEY LECTURESHIPS AND SENIOR LECTURESHIPS IN BEHAVIOURAL AND SOCIAL SCIENCES

Applications are invited from candidates with postgraduate training in one or more of the behavioural sciences especially from those with some training and/or experience in the application of their discipline in the health and medical fields. The appointees will be involved in the teaching and further planning of a new course in the behavioural and social sciences designed for medical undergraduates. The first year of the course was begun in 1974.

Salary range: Lecturer—\$A9,002 to \$A12,352 p.a.; Senior Lecturer—\$A12,648 to \$A14,724 p.a. The positions advertised are permanent ones, but may be filled for three years in the first instance, with the possibility of permanent after that time.

that time.

Applications, including curriculum vitae, list of publications and names of referees, by December 11, 1974, to the Registrar, University of Sydney, N.S.W. 2006, Australia. Further information can be obtained from the Registrar or from the Acting Head, Department of Behavioural Science in Medicine: Dr W. L. Walker.

Conditions of appointment and application procedure from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH 0PF.

(1837)

### M.R.C SCIENCE GRADUATE

SCIENCE GRADUATE
FOR BIOCHEMISTRY DIVISION
The National Institute for Medical Research has a vacancy for the post of JUNIOR TECHNICAL OFFICER in the biochemistry division. The research being carried out is concerned with the preparation and characterisation of mammalian cell membranes. As a theoretical understanding of the research would be useful, applicants should preferably have graduated in biochemistry or have studied a biological subsidiary. Salary scale starts from £1,875 p.a. plus £167 p.a. threshold agreement (maximum £2,718 plus £167 p.a.). To obtain application forms please write quoting ref. JTO/BM to Mrs M. Y. Jim, Assistant Personnel Officer, National Institute for Medical Research, The Ridgeway, Mill Hill NW7 1AA, Tel: 01-959 3666. (1842)

#### UNIVERSITY OF LONDON CHAIR OF ANATOMY AT KING'S COLLEGE

Re Advertisement—Extension of Closing date. The Senate invite applications for the above Chair. Candidates should have high scientific ability in Anatomy or related fields and a strong interest in the application of their subject to man in the context of Medical Education, Applicants need not necessarily be medically qualified. Initial salary to be aggreed but will not be less than £6,105 per annum plus £213 London Allowance. Applications (11 copies) should be received not later than February 3, 1975, by the Academic Registrar, (N) Senate House, Malet Street, London WC1E 7HU, from whom further particulars concerning the post and its special relationship with medical and biological teaching within the KTW Biomedical Centre and School of Biological Sciences, may be obtained. (1850) Re Advertisement-Extension of Closing date.

#### FELLOWSHIPS AND **STUDENTSHIPS**

#### POSTDOCTORAL FELLOW OR RESEARCH ASSOCIATE

Available immediately for research into laboratory culture and studies of larval blackflies in conjunction with the program on biocontrol. Salary commensurate with experience and qualifications. Send application etc. to Dr. M. Laird, Director, Research Unit on Vector Pathology, Memorial University of Newfoundland, St. John's, Newfoundland. (1673)

#### POSTDOCTORAL FELLOWSHIPS

opportunities are anticipated in the following areas of biting fly research program on biocontrol; 1. Ecology of larval blackflies; 2. Laboratory studies and culture of pathogens and parasites of biting flies, and 3. Field surveys for biting fly pathogens and parasites. Send application etc. to Dr M. Laird, Director, Research Unit on Vector Pathology, Memorial University of Newfoundland, St. John's, Newfoundland. (1707)

#### GIRTON COLLEGE **CAMBRIDGE**

Applications are invited for a SCIENTIFIC RE-SEARCH FELLOWSHIP open to women graduates and tenable for three years from October 1, 1975. The applications should be in the field of Mathe-matics, Natural Sciences, Geography and allied

Each Fellowship is to the value of £1,000 per annum and pensionable. Particulars are available from the Secretary to the Council, Girton College, Cambridge, to whom applications should be sent by January 8, 1975.

#### UNIVERSITY OF NEWCASTLE UPON TYNE **FELLOWSHIPS**

Applications are invited for the following Fellowships (tenable for two years from October 1, 1975) from persons who have shown themselves able to carry out original research. The value of each Fellowship is £2,118 in the first year and £2,247 in the second year.

SIR JAMES KNOTT FELLOWSHIPS

# Two Fellowships available in any faculty. EARL GREY MEMORIAL FELLOWSHIP

One Fellowship tenable for research in any faculty. As a general rule the Fellowship will be awarded to candidates who have graduated from the University of Newcastle upon Type or from King's College in the University of Durham.

Further particulars and application forms (which must be returned by December 31, 1974) may ge obtained from the Registrar, University of Newcastle upon Tyne, NE1 7RU. (1761)

#### THE WORSHIPFUL COMPANY OF SCIENTIFIC INSTRUMENT MAKERS TRAVELLING FELLOWSHIP

Applications are invited for a Travelling Fellow-ship operated in collaboration with the Massachu-setts Institute of Technology. The object of the Fellowship is to advance instrument technology in the United Kingdom. It is tenable for one or two years and it will provide facilities for an approved study and/or research programme at MIT worked out in collaboration with faculty advisers. It will head to a higher degree of the Institute.

The Fellowship is open to a suitably qualified

The Fellowship is open to a suitably qualified graduate with appropriate experience who must be a British National. It is a condition of acceptance that the holder must return to British for at least two years when the Fellowship has been completed.

For a graduate who wishes to make management in the instrument industry a career, the Fellowship may be partly or wholly carried out at the Sloan School of Management, part of MIT.

The Worshipful Company of Scientific Instrument Makers will select and nominate for approval by MIT the Fellow and will finance the applicant during the tenure of the Fellowship. Married men will have the opportunity of being accompanied by their wives and families.

Application forms, which are obtainable from The Clerk, The Worshipful Company of Scientific Instrument Makers, Alliance House, 12 Caxton Street, London SW1, must be returned by November 24, 1974.

#### UNIVERSITY OF BIRMINGHAM DEPARTMENT OF EXPERIMENTAL **PATHOLOGY**

A RESEARCH FELLOW is required to join a research team under M.R.C. sponsorship presently working on carcinoembryonic antigen and cell mediated tumour immunity. Applications are invited from graduates with research qualications and experience in related fields. Salary: £2,118 to £2,412 plus F.S.S.U.

Enquiries and applications should be made to Dr. P. W. Dykes, Department of Experimental Pathology, University of Birmingham, Birmingham B15 2TJ. (1821)

#### UNIVERSITY OF CALGARY

### DEPARTMENT OF **PHYSICS**

Applications are invited from suitably qualified persons (M.Sc. or Ph.D.) for a position as Research Assistant/Postdoctoral Fellow in the field of experimental/observational AERONOMY. Interest and/or experience in near infrared attemps/persons/science accordingly. emissions considered advantageous.

Write for further information and giving resume of background to: Professor A. W. Harrison, Department of Physics, Calgary, Alberta, Canada, T2N 1N4. (1774)

#### AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to t

#### RESEARCH SCHOOL OF BIOLOGICAL SCIENCES RESEARCH FELLOW IN NEUROPHYSIOLOGY

The successful applicant will work with P. fessor R. F. Mark. Head of the Department Behavioural Biology, on problems associated with development and maintenance of inter-neuron and neuromuscular synaptic connections. In addition to electrophysiological equipment, the Department has a neuro-chemistry laboratory, facility for electron microscopy and will be developing ethological section in the near future.

Closing Date: December 2, 1974

Closing Date: December 2, 1974.

Salaries: Salary on appointment will be accordance with qualifications and experient within the range: \$A9.002 to \$12.269 p.a. Curre exchange rates are approximately \$A1: 50 \$US1.30.

Other Conditions: Tenure: Research Fellow normally for three years in the first instance we the possibility of extension to a maximum of f

Reasonable travel expenses are paid and assignee with housing is provided for an appoint from outside Canberra. Superanneation is on 4 F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment invitation at any time.

Prospective applicants should write to the Assistant of Commonwealth Universities (Appls).

Gordon Square, London WCIH OPF for further particulars before applying.

(1805)

#### UNIVERSITY OF RHODESIA FACULTY OF MEDICINE

#### DRUG METABOLISM RESEARCH

The University of Rhodesia Faculty of Medici invites applications for pre- and postdoctor awards to undertake research in drug metabolis or associated areas of pharmacology. Successicandidates could be considered for events permanent appointment in a new department.

Research Fellow salary scales are approximate equivalent to US\$5.500 to US\$13,900 (£2.300 £5.900) with liberal fringe benefits, health insurant and return fares.

One permanent position available for physiologic Applicants should submit brief resume and quest further details from Head. Department Physiology, Godfrey Huggins School of Medicat University of Rhodesia. P.O. Box MP 167, Mon Pleasant, Salisbury, Rhodesia.

#### TWO POST-DOCTORAL FELLOWSHIPS IN THE EARTH AND PLANETARY SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites scientists interested in any field of the earth and planetary sciences to apply for the following Fellowships.

Two Post-Doctoral Fellowships, each awarded for a period of one year (extendable to two years in special instances) beginning in September, 1975, with a stipend of \$12,000 per annum. Completed applications are to be returned by February 15. Application forms may be obtained by writing to the Director, Lamont-Doherty Geological Observatory, Palisades, New York, 10964

Award announcements will be made March 31, 1975

#### UNIVERSITY OF RHODESIA DEPARTMENT OF AGRICULTURE RHODESIA CATTLE PRODUCERS RESEARCH FELLOWSHIP

Applications are invited for the above-mentionel Fellowship from Honours graduates in Agriculture, Blochemistry or Mammalian Physiology who wish to work on the endocrinology of bovine fertility. Preference will be given to condidates who are interested in developing radioimmunoassays for steroid hormones. The Fellowship is tenable for

three years.

Salary Scales and Conditions: Appointment will be within one of the following grades; entry point dependent upon qualifications and experience. (Approx. Stg. Equiv.): Junior Research Fellow Grade II £2,967 by £151 to £2,807: Research Fellow Grade II £2,967 by £142 to £3,109. Passages and allowance for transport of effects on appointment. Housing allowance, Superannuation and Medical Aid Schemes.

Applications: (6 copies) giving full personal

Aid Schemes.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience, publications and giving the names and addresses of three referees should be submitted by November 30, 1974, to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP.167, Mount Pleasant, Salisbury, Rhodesia. An additional copy should be sent to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, from whom further details may be obtained. (1796)

# UNIVERSITY OF SURREY DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY

#### RESEARCH IN ADVANCED MATERIALS

Applications are invited for a Research Appointment. The Department offers excellent facilities for research and there will be close interaction with industry.

FUNDAMENTAL MECHANISMS IN SHAPE-MEMORY ALLOYS

A post doctoral Fellowship or Graduate Research Assistantship on a 3 year S.R.C. grant to study the origins of shape-memory in alloys, Such materials are now being exploited commercially and present an exciting new field of research. The work will involve advanced metallography and physical property measurements on alloys exhibiting appropriate martensitic transformations. The salary scales are:
Post doctoral Fellows: £2,247 to £2,580 (plus Threshold Payments)
Graduate Research Officers: £1,212 to £2,385 (plus Threshold Payments).
Curricula vitae and the names and addresses of 2 referees should be sent to:
Professor M. B. Waldron
University of Surrey
Department of Metallurgy and Materials
Technology
Guildford
Surrey GU2 5XH

Guildford Surrey GU2 5XH

(1832)

(1847)

#### UNIVERSITY OF WARWICK RESEARCH FELLOW IN THEORETICAL PHYSICS

Applications are invited for a two-year appointment as a Postdoctoral Research Fellow in the Theoretical Physics Group. The successful candidate will work on the theory of hopping conductivity in amorphous materials with Professor P. N. Butcher. Salary in the range of £2,118 to 22.580 p.a. plus threshold payments and participation in F.S.S.U. Applications as soon as possible with a full curriculum vitae to the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No.: 10/A/74 (1841)

### UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PHARMACEUTICAL CHEMISTRY

#### M.Sc. RESEARCH STUDENTSHIP

Applications are invited for a research studentship to investigate the relationship between the formulation of certain dosage forms and their biological effects. The student will be expected to register for an M.Sc. degree. Payment will be at current S.R.C. postgraduate rates. Applicants, who should preferably be graduates in Pharmacy, should contact Dr A. T. Florence, Department of Pharmaceutical Chemistry, University of Strathclyde, Glasgow GI 1XW.

#### JAMES COOK UNIVERSITY OF NORTH QUEENSLAND RESEARCH FELLOW CORAL REEF BIOLOGY

The successful applicant will be expected to take an active interest in coral taxonomy, coral growth, faunal assemblages colonisation and recruitment. The project requires experience in scuba diving, transect work and a knowledge of, or keen interest in, underwater photography. Applicants must have a doctorate and appropriate research experience. Previous experience in tropical areas would be an advantage.

Salary within the range \$A9,002 to \$A12,352

would be an advantage.

Salary within the range \$A9,002 to \$A12,352
per annum plus a locality allowance of \$A142 p.a.
for a married male or \$A71 p.a. for a single
appointee. The Australian Research Grants Committee has provided funding to support the research fellowship up to December 31, 1975, in the
first instance. Conditions of appointment provide
superannuation and allowance towards travelling
and removal expenses on appointment.

Further details and application forms obtainable

Further details and application forms obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH

Applications clos November 29, 1974. (1839)

### UNIVERSITY COLLEGE OF NORTH WALES BANGOR SCHOOL OF

PHYSICAL AND MOLECULAR SCIENCES Applications are invited for a

#### SCIENCE RESEARCH COUNCIL POSTDOCTORAL FELLOWSHIP

in the School of Physical and Molecular Sciences The successful candidate will be required to work under the general supervision of Dr G. Parry Jones on the dielectric aspects of high electric field effects in molecular systems. It will be an advantage to have either experience in the dsign and operation of equipment for use in the region 1-200 MHZ or an interest in biomolecular

The fellowship which may be held for up to two years has a salary of up to £2,247 by £165 per annum plus F.S.S.U. benefits (depending on age and experience).

and experience).

Applications (two copies) giving details of qualifications, research experience and the names and addresses of two referees, should be submitted by not later than November 30, 1974, to the Secretary and Registrar, University College of North Wales, Bangor, from whom further particulars may be obtained.

(1843)

#### AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

#### RESEARCH SCHOOL OF BIOLOGICAL SCIENCES POSTDOCTORAL FELLOW MOLECULAR BIOLOGY UNIT

The Unit (Head: Dr H. Naora) is exploring the regulatory mechanism of translation in animal cells, particularly the molecular mechanism which underlies the ability of ribosomes to specifically recognised mRNA or messenger-like RNA. This includes the problems of HnRNA-mRNA pre-cursor relationship and the interaction of these macromolecules with ribosomes. Applicants should have experience in the field of RNA and ribosome research. Some experience in developing eggs and also tumor cell research would be an advantage. advantage.

Closing date: December 14, 1974.

#### **FACULTY OF SCIENCE** LECTURING FELLOW

DEPARTMENT OF BIOCHEMISTRY

DEPARTMENT OF BIOCHEMISTRY

Applicants should have a Ph.D. degree or similar qualification. The appointee will be asked to contribute to teaching programmes for graduates, honours students and undergraduate students. It is desirable, but not essential, that the appointee should have had experience in the broad field of metabolism. The appointee will be required to take up duty as soon as possible. Closing date: December 9, 1974.

Salaries: Salary on appointment to the post will be in accordance with qualifications and experience within the ranges: Lecturing Fellow \$A9,002 to \$A12,352 p.a.; Postdoctoral Fellow \$A9,002 to \$A12,352 p.a.; Postdoctoral Fellow \$A9,002 to \$A12,269 p.a. Current exchange rates are approximately \$A1—56new pence; \$US1.31.

OTHER CONDITIONS: Tenure — Lecturing Fellow is normally for three years in the first instance with possibility of re-appointment for a further two years.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation is on the F.S.S.U. pattern (where applicable) with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before applying. (1840)

### LECTURES AND COURSES

EUROPEAN MOLECULAR BIOLOGY ORGANISATION OPHYS

Postgraduate Course

### **Advanced Animal Virus Genetics** and Molecular Virology

An EMBO study course in Advanced Animal Virus Genetics and Molecular Virology will be held in the Institute of Virology, University of Glasgow from March 16th to April 4th 1975 under the direction of Professor J. H. Subak-Sharpe. The intensive laboratory periods will be supplemented by 15 lectures as well as specialised discussion. In addition there will be 7 special guest lectures.

The Course will be particularly appropriate for research workers in the field with three or more years postgraduate research experience as the programme will cover more recently developed techniques used in the genetic and biochemical analysis of animal virus systems, for example, triparental cross recombinants, restriction enzyme fragment analysis, or application of enucleate cells in animal virology. The fee is £90 excluding accommodation. The number of places is restricted to 16. Limited EMBO funds are available to help those applicants who could not otherwise attend.

For further details and application forms write to:

Professor J. H. Subak-Sharpe, The Course Director, The Institute of Virology, Church Street, Glasgow G11 5JR, Scotland. Closing date for applications is January 6, 1975.

(1754)

#### UNIVERSITY OF LONDON

A lecture entitled "The Development of Nutritional Research in Uganda" will be delivered by Dr R. G. Whitehead (Cambridge) at 5.30 pm on November 19 at The London School of Hygiene and Tropical Medicine, (Large Lecture Theatre), Keppel Street (Gower Street), WC1.

### THE EARLY HISTORY OF THE EARTH

(4.5 b.y. — 2.5 b.y.)

### A N.A.T.O. ADVANCED STUDY INSTITUTE

Department of Geology
The University
Leicester LE1 7RH
England

April 5-11, 1975 inclusive

The purpose of this Institute will be to review current data and ideas of early earth evolution from the time of the proto-crust to the end of the Archaean. It is intended to be an interdisciplinary meeting with emphasis on the following topics:

Implications of lunar to early Earth history, the proto-crust Evolution of greenstone belts, gneissic regions, the atmosphere, oceans and life forms

Geochronology and geochemistry

Thermal regimes and deformation patterns

Reflews of the structure and evolution of continental areas Metallogeny

We hope to see an exchange of information between a wide range of earth scientists who are invited to attend and participate in discussions. For the benefit of non-specialists each major topic will be introduced by a general review lecture.

There will be a field excursion before and after the meeting to the Scourian of the mainland (April 1—4) and the Outer Hebrides (April 12—16) of NW Scotland; participants are invited to apply for places on either of these excursions.

Further details and registration forms may be obtained from Dr. B. F. Windley at the above Leicester address. (1752)

# **XEROX**

University Microfilms Limited, St. John's Road, Tylers Green, High Wycombe, Buckinghamshire, England, HP10 8HR a XEROX company

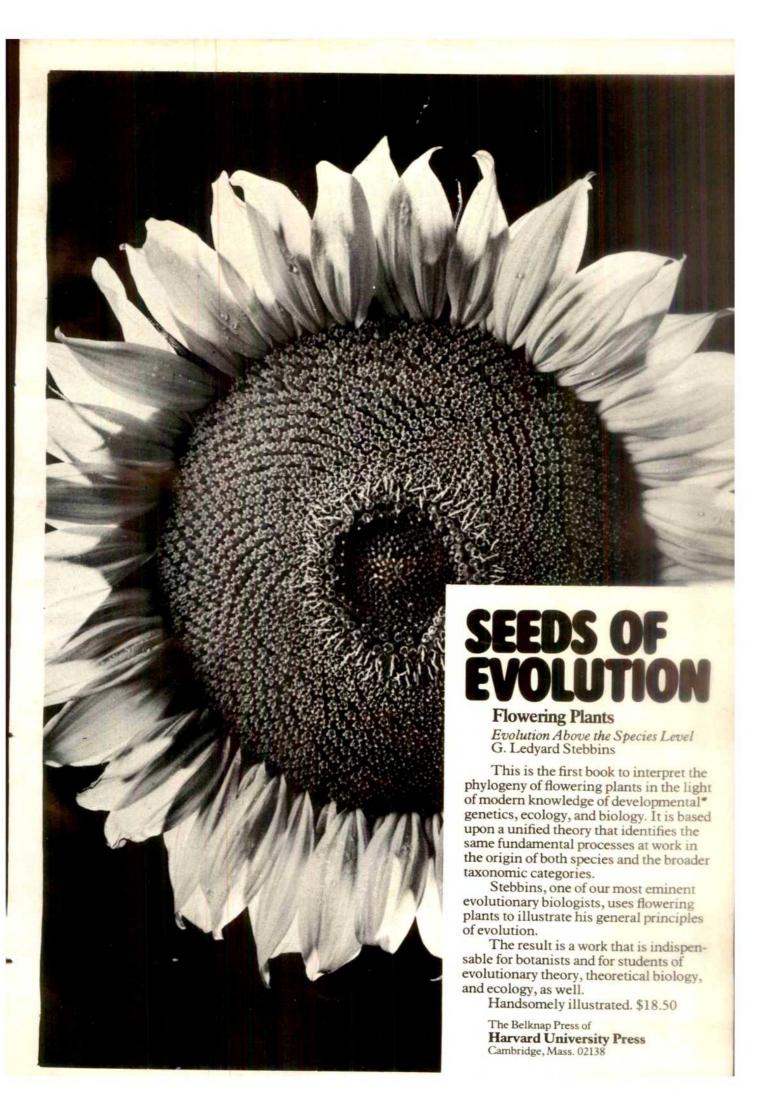

University Microfilms offer the convenient way of acquiring the most authoritative collection of science history – **Nature** backfiles in microform.

Since 1869 **Nature** has been investigating and recording the developing role of science in society, building into an unique collection of scientific thought.

As the leading international journal of the Physical and Biological Sciences **Nature** was recently voted the top international scientific journal — not surprising when it has featured the first papers on such topics as Fingerprinting, the Neutron, Synthesis of Penicillin, Structure of Haemoglobin, Sea Floor Spreading. These and many more **Nature** firsts are exclusively held by University Microfilms in microform.

We invite you to look into your periodicals library. **Nature** in microform could be the convenient way of acquiring the top scientific journal for your library – alternatively if you already subscribe to **Nature** why not complete your hard copy holdings now – in microform.

Please send me full details plus reel guide order fo	orm.

Macmillan Jeanna - Long ed

# the first year

In its first year of publication, **Cell** has published twelve issues containing almost a thousand pages and more than a hundred articles. Already **Cell** is one of the most important journals in modern biology.

# The November and December issues of Cell include the following articles:

Shaking 3T3 Cells: Further Studies on Diffusion Boundary Effects: M. Stoker and D. Piggott

Isolation of Ouabain-Resistant Human Diploid Fibroblasts: R. Mankovitz, M. Buchwald, and R. M. Baker

DNA-Dependent RNA Polymerase Activity of Chinese Hamster Kidney Cells Sensitive to High Concentrations of  $\alpha$ -Amanitin: J. L. Austoker, T. J. C. Beebee, C. J. Chesterton, and P. H. W. Butterworth

Tfm Mutation and Masculinization Versus Feminization of the Mouse Central Nervous System: S. Ohno, L. N. Geller, and E. V. YoungLai

Lineage-Dependent Transcription of Globin Genes: M. Groudine, H. Holtzer, K. Scherrer, and A. Therwath

Synthesis of ppGpp by Mouse Embryonic Ribosomes: J. D. Irr, M. S. Kaulenas, and B. R. Unsworth

Relationship of Chain Transcription to Poly(A) Addition and Processing of hnRNA in HeLa Cells: E. Derman and J. E. Darnell

Short Polyadenylic Acid Sequences in Insect Chorion Messenger RNA: J. N. Vournakis, R. E. Gelinas, and F. C. Kafatos

Metabolism of 5S RNA in the Absence of Ribosome Production: L. Miller

Synthesis of Histone mRNA Sequences in Isolated Nuclei of Cleavage Stage Sea Urchin Embryos: R. H. Shutt and L. H. Kedes

Increased Collagen Synthesis in Kirsten Sarcoma Virus-Transformed BALB 3T3 Cells Grown in the Presence of Dibutyryl Cyclic AMP: B. Peterkofsky and W. B. Prather A New Mechanism for Steroid Unresponsiveness: Loss of Nuclear Binding Activity of a Steroid Hormone Receptor: U. Gehring and G. M. Tomkins

A System for Mapping DNA Sequences in the Chromosomes of Drosophila melanogaster: P. C. Wensink, D. J. Finnegan, J. E. Donelson, and D. S. Hogness

In Vitro Synthesis of Methylated Messenger RNA by the Virion-Associated RNA Polymerase of Vesicular Stomatitis Virus: D. P. Rhodes, S. A. Moyer, and A. K. Baneriee

Isolation from BALB/c Mouse Cells of a Structural Polypeptide of a Third Exogenous Type C Virus: J. R. Stephenson, S. R. Tronick, and S. A. Aaronson

Cellular Tumorigenicity in *nude* Mice: Correlation with Cell Growth in Semi-Solid Medium: V. H. Freedman and S. -i. Shin

Alterations Leading to Increased Ribonucleotide Reductase in Cells Selected for Resistance to Deoxynucleosides: M. Meuth and H. Green

The Effect of Cyclic Nucleotides on Purine Biosynthesis and the Induction of PRPP Synthetase during Lymphocyte Activation: D. A. Chambers. D. W. Martin, Jr., and Y. Weinstein

#### The first issues of 1975 will contain:

Changes in RNA in Relation to Growth of the Fibroblast. III. Posttranscriptional Regulation of mRNA Formation in Resting and Growing Cells: L. F. Johnson, J. G. Williams, H. T. Abelson, H. Green, and S. Penman

The Size of Fibroin Messenger RNA and its Polyadenylic Acid Content: Paul M. Lizardi, Robert Williamson, and Donald D. Brown

Cell

The Length of the Fibrion Gene in the Bombyx mori Genome: Paul M. Lizardi and Donald D. Brown

Biosynthesis of Rauscher Leukemia Viral Proteins: Robert B. Naso, L. J. Arcement, and Ralph B. Arlinghaus

#### Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major résearch developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures Typing (including references) should be double spaced. The title should be brief and informative. Pages should be purphered. be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e" if 'a' is more than one character Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. See any contemporary Nature for style, but note:

- (i) To refer to several references by the same author at once, only one reference number need be given.
  - (ii) Cite first and last pages.

Abbreviations should follow the World List of Scientific Periodicals, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-bepublished volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of Nature. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. We are always glad to see artwork for possible use on the cover, whether or not it is associated with a manuscript, but cannot guarantee the return of material.

A fuller guide appeared in Nature (246, 238; 1973).

# Getting scientists interested in policy

Science policy begins to bite—that is a clear message emerging from the annual reports of many bodies supporting science, and most recently from the Science Research Council (SRC), guardian of £70 million of British research from neurobiology to high energy physics. The message comes equally from the international organisations.

For years the last thing that most practising scientists wanted to know about was the machinery by which policy for science was evolved. After all the money generally could be relied on to roll in provided the proposal sounded plausible enough and dreary matters of policy could be left to those amiable and harmless civil servants in London, reinforced with sensible and central professors prepared to commute to endless committee meetings. We neither knew nor cared who they were, what they did in our name or how we were represented in international organisations because the funding was sufficiently pluralistic that if A regretfully couldn't provide, B probably would. And we were mercifully spared from Five Year Plans and the like, which we knew stultified Soviet science, for example. Even when a little forecasting was done and there was talk of shared facilities. we knew that if we produced the goods we would be allowed to go our own way.

The first shock came, of course, in the very late 1960s when university expansion ended and the devaluation of sterling was indeed starting to get at the pound in our pockets. But the real blows have come within the past two years when the budgets for science has been unable to keep up either with rising costs or with the ever increasing demands that scientists make on it. Added to this, universities find themselves with insufficient funds to guarantee that vacant posts can be filled. So the words priorities and planning will assume a greater significance and scientists will find themselves increasingly subject to decisions made for them by councils and committees. The words in the SRC report "... the Council have provisionally concluded ... that the priorities for astronomy, engineering and the area supported by the Science Board should be sharpened at the cost of reductions in other expensive programmes . . . " can only be a foretaste of what is to come in straitened times.

It is impossible to argue with this in principle. If the government pays, then the government has the right to assert priorities. Moreover in some respects, particularly at the moment as regards questions of manpower, one could wish for more central direction. Do we really want to see, in the absence of some corrective pressure in schools and universities, a continuation of such trends as those which lead to many astronomers and few chemists? Nevertheless the very lack of prior interest in science

policy among most scientists raises some important questions.

To what extent are those who make and implement policy responsible to the scientist whose livelihood may be threatened? The short answer is not at all, neither in terms of being elected by him nor in terms of being required to discuss decisions with him. This is hardly to say that if you call up, say, the SRC and ask for extension 1 you will not be able to speak with the chairman. You can, and he doubtless will give a civil reply. Mechanisms do not exist, however, for ensuring that the grass roots has any say whatever in the appointment of those in authority or who represent the United Kingdom internationally. No more do they exist for requiring that decisions be open to scrutiny, criticism and maybe modification in the light of this criticism.

It is not obvious that the system by which scientists are appointed rather than elected should be changed. Much dedicated work is done by people who would have no stomach for an electoral process and in the absence of party labels most electors confronted with a list of names about which they know nothing will vote at random—and in any case, who votes? But one would have greater confidence that an election was unnecessary if there were more frequent occasions on which rank-and-file scientists could listen to their representatives explaining decisions and listening to opinions. This is partly the function of the scientific press but mainly it needs some regular forum where scientists can get together.

This would be an ideal function for the British Association (BA) to perform. We have already proposed that the BA should take a more active role in making scientists more aware of their common interests by the forming of local cells, and one of the most valuable things that such cells could do would be to generate an enhanced interest in the questions of decision-making on scientific matters at governmental level. Such regular opportunities to talk about the problems at the top could hardly be other than most welcome to those who have, in the name of scientists, to try and share out a diminishing cake.

### A hundred years ago

The commotion created in th: Paris School of Melicine by the false rumour spread by the Figaro has been beyond bounds; not only was M. Wurtz, the Dean, cheered, but M. Chauffard, one of the professors belonging to the clerical party, was hooted, and unable to deliver his lecture. The disorder having been renewed in spite of all precautions taken by M. Wurtz, the School of Melicine has been closed for a month. If students again exhibit a riotous spirit, the ringleaders will be prosecuted before a Council of War; which is a lawful proceeding, Paris being placed under a state of siege.

### Weather warning: you are now experiencing a climatic change

John Gribbin has recently been visiting climatic research centres in the United States and Canada as part of a Glaxo Travelling Fellowship. In this article he discusses work now in progress, the hopes of some of the scientists active in the field, and the pressing need for more research in view of world food problems.

The name of Reid Bryson, Director of the Institute for Environmental Studies (IES) at the University of Wisconsin-Madison, is one which arouses strong response from most climatologists and meteorologists. His outspoken views on the imminence of global catastrophe and on the form of food shortages, and the degree to which he blames man's activities for the decline in global temperature over the past two decades, are either taken at face value or fairly strongly opposed—there is no middle ground.

Bryson and his group are particularly concerned with two aspects of the changing climate: determining precise quantitative parameters of past climates from analysis of pollen samples and predicting the development of present climatic trends, with special reference to the problems of food production. The former line of study causes no breast beating even among Bryson's most vociferous opponents. In its latest form, this study involves analysing pollen from the sediment layers (varves) in cores obtained from lakes in the north-eastern United States. The thickness of the varves, laid down in successive years, provide a guide to the year-by-year changes in mean climate; but that is at best a crude measure and the application of pollen analysis to the cores provides potentially the best indicator yet of how past climates have changed.

The continuous varve sample goes back for some 9,000 years—a longer and more complete record than the tree rings which have already proved so useful to climatologists. They provide more information over the whole span and there is the additional bonus of inorganic material from the sediments which provides other information about age and climate. So far, the Madison team has established a clim-

atic chronology made up of one sample per decade over the 9,000-years; work is now in progress on more detailed studies.

The facts which emerge from the analysis of past climates often encourage dramatic presentation. Bryson mentions "sharp" changes occurring within 17 years which are revealed by pollen studies. Meteorologists have argued that the atmosphere simply cannot change dramatically in such a short time, but, as Bryson puts it, "the theories must be made to fit the facts, not the other way around". And the facts he presents certainly require urgent explanation, suggesting as they do that it is possible to go from an interglacial regime (such as the present situation) to full glacial conditions in only 100 years.

According to Bryson, man's activities as an atmospheric polluter have reached a stage where that may be exactly what we are in for. Like many other climatologists, he sees volcanic activity as a prime cause of past changes, because of the effect of dust on the transmissivity of the atmosphere. Unlike some of his contemporaries, however, Bryson is convinced that man-made 'dust' is now producing a cooling trend as significant as any recorded effect of volcanic dust. In his own words "the troposphere shows clear evidence of a man-made effect since the 1940s", and this corresponds to the global cooling which has been going on since about that time. Bryson rejects the suggestion that variation in the Sun's activity could be responsible for a major part of this trend. "Don't tell me this is a major effect-how could it be physically?" was his response to my suggestion that the possibility deserved further study. This response was not entirely convincing, however, in the light of his own remarks about the need for theories to fit the facts, rather than the reverse.

Still, even if he does not go along with this particular controversial idea Bryson has plenty of publicity-worthy ideas of his own. Some of the latest work to emerge from the IES points to a relation between the incidence of condensation trails produced by jet aircraft over the North Atlantic, loss of sunlight and reduction in the euphotic zone of the oceans, a reduction in nutrients, and a delay in warming, which produces less plankton at a later time in the year than would

otherwise be the case. This delayed and decreased bloom of zooplankton is just what has been observed since 1950, selectively under the jet route, according to Bryson's figures.

But in spite of the 'gee whizzery' of such attempts to arouse public interest in the problem of climatic change there is an underlying seriousness to this work which justifies all the publicity-grabbing efforts. Bryson and his colleagues have produced projections of the fall in world food reserves which ought to be enough to shake even the dullest politician. By 1975, we could reach a situation in which only 8 to 10 days' supply of food remains in reserve—and the food distribution 'pipeline' needs 8 days' supply to keep things moving as they are ... present. This bears out calculations by the World Meteorological Organisation (see Nature, 250, 176; 1974) which highlighted the fact that there are no longer any substantial reserves of either food or unused farming land available. And it is his efforts to publicise this situation which are seen by other climatologists as Bryson's chief contribution to the problem of tackling present climatic change.

There is certainly a growing public awareness in North America of the fact that something is going wrong with the weather. The driver of the airline bus in Madison commented on the early frosts which have affected local farmers drastically, and a TV weather forecaster on a Chicago station commented in passing on the "three early cold waves which haven't done much good for the food situation". Stephen Schneider, of the National Center for Atmospheric Research (NCAR) in Boulder agrees that the food situation is worrying, but stresses the sense of urgency conveyed by Bryson's work without echoing his sense of certainty.

According to Schneider, we do not know enough about the natural processes of climatic change, or about man's influence, to be dogmatic. As Francis Bretherton, Director of NCAR put it, climatic research has been the "Cinderella of the meteorological sciences for the past two decades"; at present we are still at the stage of planning and getting a programme together. But unfortunately the deterioration in climate, if it is real, will not wait for the necessary research to be carried out. Schneider sees the possibility of a severe famine situation in

Reid Bryson of IES: outspoken views on imminent global catastrophe.

Ethiopia this winter as just one example of the immediate problems to be faced.

For the past 10 to 15 years the world climate has generally been good for food production, but bad husbandry and lack of foresight has produced a crisis situation. Supply and demand are now too close for comfort; Schneider believes that even three years ago it would have been possible with good husbandry to provide for all except the most extreme weather conditions, but now we need good weather for several years simply to get back to a marginal position of safety. The problem, he says, is man-made—but in the sense of being man-made foolishness, not technological.

In the long term the situation still looks bleak to Schneider. Although the problems to be solved are within the abilities of modern technology (in terms of increased yield per acre, improved standards of living and simply better 'housekeeping') the kind of budget and effort required would rank with the present military budget of the United States. In those terms, the problems look insurmountable simply in a political sense.

In spite of this gloomy prognosis, workers at NCAR and elsewhere continue to tackle many aspects of the changing climate situation with an increasing level of activity. If we can survive the immediate crisis which has been produced as a result of the interaction of population, food supply and climate, then we will be much better armed to tackle similar problems in future. Studies such as that by Warren Washington (NCAR) of the importance of waste heat from power stations and an investigation by Canadian meteorologists into the effect of reservoirs on precipitation are typical of the kind of problems which could, and should, have been tackled ten or more years ago and which are essential if the world is to continue to support anything like the present level of population.

The Canadians—notably the Meteorological Applications Branch of Environment Canada—have an enviable reputation for foresight because they possess equations relating wheat yield to the weather in Canada in any particular year. This, however, is more an accident of history than anything else, as the Branch's Director, Gordon Mackay, is quick to point out. The entire economy of Canada is so dep-

endent on wheat that this problem was tackled from an economic viewpoint, not through any concern about world food supplies. Nevertheless, the result is that the Canadians do have an existing working technique for determining wheat yields, and this could well be adapted to forecasting crop variations in other parts of the world.

Mackay is adamant that with the limited staff and resources at his disposal the Meteorological Applications Branch must consider primarily problems which affect Canada, although, of course, he recognises that this requires some understanding of the circulation of at least the Northern Hemisphere. Indeed, Mackay says that meteorologists in Canada would not really be aware of the changing climatic situation without the speed of modern communications; in parochial terms, they have no real problem as yet, although farmers have begun to switch to crops which require a shorter growing season, to such an extent that some kinds of seed grain are now very difficult to find.

This, perhaps, points to one immediate way in which the twin problems of food and climate can be tackled even before a full understanding of climatic change is developed. Farmers around the world must give up their traditional crops if these are not producing good yields and turn to the kinds of crops which can be grown satisfactorily in the conditions now prevailing. Echoing the sentiments expressed by Schneider, Mackay said that 50% of the world food supply is wasted by bad management or des-

troyed by pests and disease, some of these, such as rust, themselves being related to climatic factors.

The outlook is certainly gloomy, unless governments do a lot more than just talk about the problems at such gatherings as the World Food Conference. And it is no use for the holders of the purse strings to expect that a sudden change of heart on their part will belatedly lead to dramatic new revelations about how climate is changing and what influence this is likely to have on food supply. As Mackay put it, the situation today in climatic research is not unlike the situation in meteorology a hundred years ago. At that time, the Canadian Meteorological Service was founded to provide storm warnings, and functioned at first more or less on the principle of hoisting a warning to tell shipping "you are now in the middle of a storm"; today, the descendants of that service can tell us "you are now experiencing a climatic change". How big that change is, which direction it is moving in and just what effect it will have on the human population of our planet are all questions which can be answered quickly only if climatic research is far greater priority than it has received so far. The overall impression gained from talking with those active in these studies today is that the effort needed is comparable only to the effort of a full scale war, and without this effort then a major 'crunch', in the form of famine, disease, war or some combination of the three, will inevitably reduce the world population drastically within a few years.

## nternational news

WHEN New Delhi was chosen three years ago as the site for the 26th International Congress of Physiological Sciences, the Indian government gave assurances that nobody would be prevented from attending on the basis of race, citizenship, religion, political philosophy, language or sex. But when the event took place last month, visas were denied to scientists from Taiwan? Portugal, Rhodesia and South Africa. and scientists from Israel were only permitted to attend after attempts to exclude them drew strong international protests.

Those events, which are of course commonplace for conferences held in the Soviet Union, have been brought to the attention of at least one influential international scientific body, with the result that India is likely to slip a few places in the list of desirable locations for scientific jamborees.

New Delhi was selected as the site for this year's meeting by the General Assembly of the Internatioal Union of Physiological Sciences (IUPS) in 1971 but it was not until this summer that it became known that the Indian government intended to deny visas to scientists from five countries with whose policies it disagreed. Although no official

### **India** barred conference delegates

reasons have been given, it is generally assumed that the Israelis were to have been excluded because India wanted to stay on the right side of Arab oil suppliers, the Taiwanese because of Taiwan's expulsion from the United Nations, the Portuguese because of Portugal's colonial policies in Africa, and the Rhodesians and South Africans for obvious reasons.

When the news reached the United States National Committee for the IUPS, it immediately called the matter to the attention of the International Council of Scientific Unions (ICSU), a major international scientific body, and asked the Foreign Secretary of the National Academy of Sciences to open negotiations with the Indian Embassy in Washington.

At the same time, a delegation of physiologists in India met with the Prime Minister, Indira Gandhi, to try

to persuade her to allow free access to the meeting.

An ICSU General Assembly, held in Istanbul a month before the IUPS Congress, passed a resolution to the effect that repeated incidences of restrictions on free communication between scientists would result in the ICSU advice to its constituent unions not to plan scientific meetings in such countries

As a result of those pressures, the Indian government relented a little by granting Israeli scientists 21-day landing permits, but it held fast on its decision to exclude Taiwanese, Portuguese, Rhodesian and South African participants. One factor in the decision to allow Israeli participation was probably the fact that three symposia associated with the congress were being held in

It turned out, however, that no Rhodesians or Portuguese registered to attend and that the one South African who applied held a British passport. (He later elected to stay away when his South African wife was refused a visa, however.) But five Taiwanese who wanted to attend the meeting were refused visas and thus were excluded from the conference.

INDIA'S Fuel Policy Committee (FPC, set up in 1971 in the Planning Commission to project a long term energy picture for the country) has finally submitted its report to the government. The Arab Israeli war of October last year had apparently caught the FPC napping; it was all set to submit its report in December 1973 but found to its chagrin a good number of its energy board comprising representayear for the FPC to surface again with a report.

design her energy policy for the next But it has also urged that priority installation of 'captive' power stations few decades on the assumption that should be given to exploration for oil coal rather than oil would be the and uranium. energy base of India's economy.

energy needs by the end of the Fifth plants for more effective utilisation of Plan period (1978-79) is as follows: this resource in the domestic and rural 135 million tonnes (Mt) of coal; 34.4 sectors. (Incidentally, gobar gas had committee's view, reserves of coking Mt of mineral oil and petroleum pro- not found any mention in the FPC's ducts; 120 billion kW h of electricity and 123 Mt of firewood, charcoal and about to submit in December 1973). because of the expected industrial dungcake.

policy, the FPC has made suggestions for administrative reorganisation; it would like the government to set up an energy commission and also an

The FPC has strongly recommended The committee's forecast of India's popularisation of gobar (dung) gas

To give effect to a coherent energy suggested that hydroelectric schemes on five-fold within the next 20 years.

river systems to the extent of 80 to 100 million kW capacity, be investigated and installed within the next 20 to 30 years. It would also like power stations to be set up at coal pithead sites to ease pressure on movement of coal to existing distant thermal stations.

With regard to nuclear power, the FPC expects that by 1985-90 the country's uranium resources will be able to support an installed capacity of 6 to 8 lakh MW for three decades, and that by that time fast breeder reactors too will have come on line to turn thorium (which India has in great abundance)

The FPC is not enthusiastic about by industries (private or public) because, in its view, that would not be in the "overall national interest".

On energy research and development, work on conservation of coal should be given urgent attention since, in the coal are not expected to last much earlier energy projection which it was longer than 40 years or so, whereas For power generation, the FPC has growth coal requirements will increase

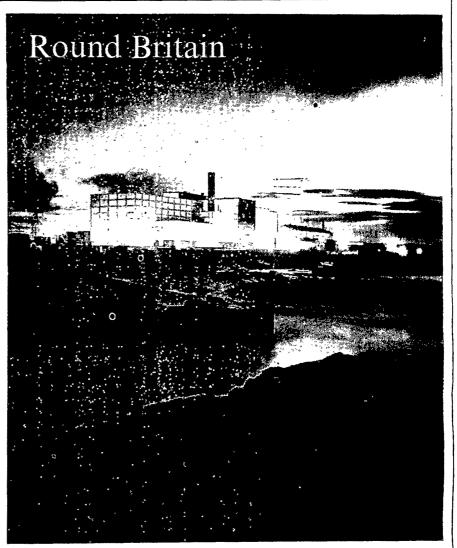

In view of the emergency cuts in public spending last December, the Science Research Council (SRC) will have in real terms 2% less money to spend in the next year, but promises in its annual report that direct grant support to the universities will be maintained at the present level—reassuring news in the present financial crisis. The real cut in expenditure rather than the planned increase of 1½% will mean, however, that the council has to defer a number of major projects. A large slice of the SRC's budget (about onethird) goes on international projects such as ESRO, CERN and the reactor at the Institut Lane-Langevin, and fluctuating exchange rates over the past year have inflated the real contribution to international programmes.

The probable cuts in university expenditure on research loom large in the SRC's thinking for the future. The cutback in university spending is likely to throw more of the burden of supporting basic research on to the SRC at a time when their funds are not increasing.

This will mean that the SRC will have to be much more selective about new projects to be supported. Provisionally, the council has decided that the growth of postgraduate studentships should not be more than 1% a year and that astronomy, engineering and the activities covered by the Science Board (genetics, enzyme technology, neurobiology and various branches of physics and chemistry which do not come under the other boards) should according to Mr R. V. Moore, Man- Congregation". Scientists predominate, be given priority at the expense of some other programmes. The establishments run by the SRC will also have to face a period of restraint to help raise resources for new facilities which only the council can provide.

## What effect will the new faces have?

from Colin Norman, Washington

THE results of last week's elections in the United States are simple to relate. The Democrate strengthened their hold on Congress, and they now occupy more than two-thirds of the seats in the House of Representatives and three-fifths of the seats in the Senate. (All members of the House of Representatives were up for re-election and one-third of the Senators.) The new Congress, which takes office in January, will be younger and probably more liberal than the present one, and there will be more new faces on Capitol Hill than at any time since the Second World War.

What do these changes mean for science? It is important to bear in mind two factors. The first is that because of the so-called seniority system, under which committee chairmanships are given to the longest-serving members of the majority party, the newcomers will have little direct power. Few committee chairmen will be leaving this year and therefore the people who wielded the power in this Congress will continue to pull the strings in the next. The second factor is that party labels don't necessarily mean much when it comes to voting on specific issues since there is a wide spread of political opinion among members of both parties.

Nevertheless, there are a few changes in important positions on committees which deal with science and technology, with the Joint Committee on Atomic Energy being the most directly affected. Six out of the eighteen members of that committee either lost in last week's election or will be retiring at the end of this year, and the departures include two of the most influential members -Chet Holifield and Craig Hosmer. Since virtually every member of the joint committee is now a firm supporter of nuclear power, if even as few as one or two of the vacancies are filled by environmentalists or other nuclear sceptics the result would be important in changing the way the committee conducts its affairs.

Another significant departure is that of John Davis, the Chairman of the House Subcommittee on Science, Research and Development, who lost a primary election earlier this year. That subcommittee is the focal point for deliberations on general science policy matters in the House of Representatives and it also oversees the workings of the National Science Foundation. Davis's place will probably be filled by James Symington, a young and widely respected legislator from Missouri who

can be expected to step up the pace of the subcommittee's activities. Davis was also a member of the governing board of the Office of Technology Assessment and was in line to be its chairman.

Aside from direct dealings with science and technology, the new Congress is expected to be more sympathetic to environmental concerns because several Congressmen and Senators opposed by environmental groups were defeated. Among them were eight Congressmen listed earlier this year as the House's "Dirty Dozen" by a group called Environmental Action. In addition, twelve of seventeen candidates supported by the League of Conservation Yoters were successful in the polls.

Those results have been greeted by environmental groups as proof that, in spite of the present concern about energy shortages, environmental issues are still politically potent. In particular, the results from Colorado indicate that environmental concerns there played a strong part in the election of a Senator, the Governor and at least one member of the House of Representatives. The upshot could be a setback to the government's plans to promote the extraction of oil from shale and the production of natural gas from deep deposits under the Rocky Mountains.

In the Senate election, Gary Hart, who was Mr McGovern's campaign manager in 1972, defeated Senator Peter Dominick after lambasting Dominick's voting record on environmental matters. As for the governorship, a state legislator, Dick Lamm, who had strongly supported laws to control urban growth in Colorado, defeated the incumbent governor. And in addition, Colorado voters approved a proposition on their ballot papers that before any more underground nuclear blasts can be set off in that state as part of a programme to extract natural gas from tight deposits, a referendum must first be held. The result of that move is likely to be the final blow for the Atomic Energy Commission's Plowshare Project.

Furthermore, environmentalists have hailed the election of other state governors, such as Edmund Brown in California and Edward Herschler in Wyoming, who are considered to be sympathetic to their views.

The election results may also portend some changes in the area of health, since many Congressmen supported by the American Medical Association (AMA) were defeated. One possible result may be to improve the chances that Congress will give its approval in the next two years to a meaningful national health insurance scheme. The AMA, which is vigorously opposed to

anything but a minimal health insurance scheme, poured about \$1 million into the campaign chests of Congressmen who supported its policies.

Perhaps the over-riding concern during the election campaign, however, was inflation and that will also have a direct bearing on the way in which Congress deals with some scientific matters. The Democrats have now been given a strong electoral mandate to curb inflation and they will be likely during the next two years to keep a strong hand on the federal government's purse strings, with the result that few controllable items in the budget will be allowed to grow. Energy research and development can be expected to escape the worst of the squeeze and so, perhaps, can such politically sensitive areas as cancer research. But for the rest of the science budget, a period of austerity should be anticipated.

## Soviet failure on the moon

from Vera Rich

One of the happier results of Soviet-United States cooperation in space research must surely be the increasing openness of the Soviet planners about their failures. In the early days, the possibility of failure did not exist—aborted interplanetary craft were discreetly registered under the cover-all of the Kosmos programme, and probes which failed to send back data were said to have "completed their mission" by the mere fact of effecting a landing or fly-by. The announcement of the Luna-23 failure comes with rather startling frankness.

True, 1974 has not been one of the most spectacular years for the Soviet space programme. Three out of four Mars probes failed to operate on reaching the planet, and the rather coy manoeuvering of the manned Soyuz-15 around the unmanned Salyut-3 in August caused wide speculation that a link-up had been originally intended. In these cases, however, the TASS reports did suggest certain positive achievement. However, Luna-23, launched on October 28 in good time for the Revolution Day celebrations, and hailed as part of the festal "illuminations" in a Pravda article of November 6, seems to have been officially recorded as a failure. Intended to carry out drilling operations to a depth of 2.5 m, it touched down in a rough area of the Mare Crisium, wrecked its drilling gear, and, after transmitting data for three days (which coincided neatly with the Revolution holidays) ceased functioning.

## correspondence

### Mosquito research

SIR,—The article by Narender K. Sehgal (Nature, September 20) entitled "Doubts over US in India" is misleading and misinformed. The article repeats some of the allegations which have been made during the past few months in the Indian press about current mosquito research in Delhi, but it omits many subsequent retractions in the same press.

The Research Unit for Genetic Control of Mosquitos in Delhi is a joint venture of the Indian Council of Medical Research and the World Health Organisation. The unit was established about five years ago to study the ecology of three of the major disease vectors of India, Culex pipiens fatigans, Aedes aegypti and Anopheles stephensi, and to investigate genetic mechanisms which might be utilised for their control. All three are difficult to control by conventional methods, not only in India but throughout their distribution range. The research programmes were planned in India by ICMR and WHO scientists who, collectively, represented a range of disciplines and who shared a wide experience of vector-borne diseases. It is clear from the erroneous and misleading statments on filariasis, dengue and malaria that neither Mr Sehgal nor his informants are qualified to judge the scientific aspects of the programme, which makes it all the more reprehensible that they themselves have not taken the "closer look at the related details" of the "seemingly scientific investigations" which they recommend to others. The details are readily available. A whole issue of the Journal of Communicable Diseases published in the middle of 1974 in Delhi describes the programme. There is no secrecy, as has been charged; about the work. Having been closely associated with the unit and its staff for five years, both as a consultant and Project Leader, I can give this assurance unreservedly.

The main charge in the controversy, unfortunately still current, is that the data being collected on mosquito ecology may be, or are being, misapplied in some fashion relating to biological warfare. The same charge could equally well be laid in India and elsewhere against work being done on insect vectors of plague, viral encephalitis and typhus. The results from a great deal of biological and medical research could in theory be misapplied,

but this is a poor argument for criticising studies specifically designed for the long-term benefit of the community. If the interpretation of current mosquito research presented by Mr Sehgal is genuinely believed by some non-medical Indian authorities, then there is clearly a said lack of understanding of the integrity and objectives both of local and foreign scientists in India and of international agencies.

There is nothing unusual about the financial support of the mosquito unit from US PL480 Indian funds. Scores of other research projects in India carried out by Indian scientists have been supported from the same source. The political implications that have been made have damaged relationships within the medical science community, and their continuance can only hinder progress in controlling mosquito-borne disease.

Sir Ronald Ross often expressed his frustration and discouragement when his research in India on Culex pipiens fatigans and bird malaria, which subsequently won him a Nobel prize, was misconstrued and retarded by the authorities of his day. It will be disheartening if, 75 years later, his successors suffer the same discouragement.

W. W. MACDONALD Liverpool School of Tropical Medicine, Liverpool, UK

#### **Protests**

SIR,—My letter published in your issue of August 12 set out the unequivocal policy of the World Federation of Scientific Workers on the rights of scientists to work and the procedure for implementing this policy in specific cases. Professor Janouch (Nature, September 20) does not approve of our policy and believes that "only open, public stands, protests and statements are meaningful and helpful". My own experience in working in international organisations over many years has taught me that, from the point of view of helping individuals in difficulty, not less than preserving the integrity of the organisation, an informal, low-key approach may often be more effective than the attitude he advocates.

Surely, also, before making protests and statements one should seek to discover whether the facts of the case have been fully and accurately presented. This is what our procedure tries to do and often, as in fact has hap-

pened in the particular case that led to this correspondence, new facts show the matter in a somewhat different perspective.

The case of Professor Holzer, referred to in Dr Janouch's letter, is much more serious than he claims because it is based on a law existing already in certain West German Länder and currently being prepared for submission to the Federal Parliament, whereby a whole category of people, members of certain legal parties and organisations, such as the German Communist Party (DKP), can be debarred from employment in public service posts, including posts as school teachers, judges and university teachers.

Dr Janouch also mentions the case of Academician Ivan Malek, who gave dedicated and distinguished service to the Federation over many years. Those who have heard or read addresses I have made to meetings of the Federation in recent years will be in no doubt about the high esteem and affection in which he is held in the Federation. Academician Malek was an active supporter of Alexander Dubcek and lost his posts as Director of the Institute of Microbiology in Prague and as a Vice-President of the Czechoslovak Academy of Sciences in the aftermath of the events of August 1968. Together with other officers of the Federation I made representations on his behalf at a high level with a view to ensuring that necessary facilities to enable him to continue his scientific work were made available to him. Although, however, he continued to work in the Institute he was not restored to his former position. According to information supplied to me from official quarters his work at the Institute terminated last autumn when he was three years past the usual retiring age of 60 for scientific workers who do not hold university chairs.

Academician Malek is a most distinguished and talented microbiologist who, in my opinion, still has very much to give both to Czechoslovakia and to world science. Speaking personally, therefore, I would deplore a regulation obliging a scientist to retire while still capable of first class scientific work no matter in which country it occurred. Nevertheless, one must surely concede that questions such as retirement age in a particular country are matters for the people of that country to determine.

World Federation of Scientific Workers, London, UK

## news and views

# Towards chemical topology

THE uninitiated, faced with the awesome variety of organic chemistry, its peculiar, cryptonymous nomenclature and its tendency to produce publications in twenty or thirty parts, might be excused for finding there more to excite the wonder of the natural historian than the rigours of mathematics. Neither is the practitioner sketching formulae in the odorous intimacy of the laboratory likely to ascribe much abstract significance to the cyphers which he learns to manipulate as by second nature. Yet the business of classifying and labelling the complicated ring and branched structures which figure so prominently in the modern subject has been recognised in recent years to involve far more than simple book-keeping; in fact some of the problems which arise, when stripped to their abstract essentials, connect with as yet unresolved difficulties in the area of finite mathematics usually termed graph theory.

Consider, for example, the following: can a coding system be devised which not only leads to the systematic reconstruction of an arbitrary carbon skeleton but which is essentially independent of the particular way adopted for labelling individual atoms or other distinguishing features? Alternatively, if a certain labelling system is adopted (usually, of course, that of attaching sequential numbers to the carbon atoms present) can coded representations be found from which the topological identity of two differently numbered versions of the same N-carbon structure can immediately be inferred? (Other, that is, than by investigation of all possible N! permutations of labelling.)

This problem, which shares its graph-theoretical content with several others in statistical mechanics and the theory of disordered structures, has been taken up in a number of recent papers, most notably by M. Randić of the University of Zagreb writing in the Journal of Chemical Physics (60, 3920; 1974). Professor Randić advances no rigorous proofs but suggests an ingenious algorithm by which a binary number code is assigned to each possible labelling of a given structure, the lowest number obtainable under systematic rearrangements providing both a canonical numbering scheme and an immediate comparison test for the identity of different networks of bonds. The method given seems to fall short of guaranteeing the discovery of the minimal labelling but seems to work well when tried on the common systems of saturated and benzenoid hydrocarbons. Needless to say the canonical numbering systems come out differently from those traditionally adopted. (It is notable, and amusing, that the basic tool of the Randić method—the adjacency matrix for comparable structures—is now a familiar part of O-level mathematics (see Schools Mathematics Project Book Y, 55; Cambridge University Press, 1973) though likely to seem formidable to many research chemists educated in an earlier era.)

The recent involvement of stereochemistry with topics such as graph theory, the less usual point-group geometries, the interconversion of symmetry types and the combinatorics of multiple structures, is an encouraging sign that this subject, cutting across all the main disciplines of chemistry, might be prominent in any defence of the latter

against charges of moribundity and compartmentalism.

A very timely cross section of contemporary (organic) stereochemical research, as well as a useful reminder of the heroic era of the subject is to be found in the recent van't Hoff-Le Bel centennial issues of Tetrahedron (30, Nos 12, 13; 1974). Here some fifty papers are collected covering topics so various, and occasionally bizarre, as to make selective quotation at best misleading. Among the less orthodox papers are those on "Polytopal Form and Isomerism" (E. L. Mutterties, Cornell), "High Symmetry Chiral Molecules" (M. Farina and C. Morandi, Milan/La Jolla), "Polyhedral Rearrangements Involving 5 and 6coordinate Carbon" (M. F. Hawthorne, K. P. Callahan and R. J. Wiersma, UCLA), "Knot-structures in Chemistry" (J. Boekmann and G. Schill, Freiburg), "Parity and Stereochemistry" (J. Mathieu and A. Rassat, Grenoble) and "Chemical Systematics in the Computer Design of Syntheses" (J. Blair, J. Gasteiger, C. Gillespie, P. D. Gillespie and I. Ugi, Munich). The last mentioned also involves the graph theoretics of labelling, the time in the enumeration of synthetic pathways by computer. Many exotic systems make an appearance—cyclophanes, propellanes, carboranes—among others less strange though scarcely worked out stereochemically, such as tetra-aryl methanes. A disappointment perhaps is the non-appearance of the marvellous and unique dodecahedrane, which several groups have been rumoured to be close to synthesising, perhaps the most beautiful hydrocarbon that will ever be made.

Yet the outsider looking in at such intricate and painstaking work cannot escape certain mixed feelings. Granted that there is a place for jeux d'esprit in such a collection, how important is it to the future of chemistry that someone should succeed in synthesising a molecule with a knot or a peculiar kind of hole in it or a particularly awkward linkage of rings? And, if dodecahedrane can be made, should we take comfort in the fact that rhombic dodecahedrane is manifestly impossible? In short, are these weird and wonderful aspects of stereochemistry outgrowths of a flourishing field, or hot-house creations of almost zero relevance to either the theory or the application of the subject? Should one not, after all, admit that chemistry has become little more than a complicated and private 'bead-game'? The riposte to this no doubt lies in pointing to the considerable achievements of mainstream stereochemistry—conformal analysis, the Woodward— Hoffmann rules, and the various aspects of 'kineticstereochemistry'—which have come into their own recently, while stressing the underlying biochemical relevance of much (though by no stretch of the imagination all) that has been done. This line is taken in a recent interview given by Alexander Todd (Chemistry in Britain, 10, No. 6, 207; 1974) who argues with impressive conviction, if not altogether convincingly, that with sufficient imagination and resources, genuinely new and relevant phenomena will continue to be found. Given that it is not an entirely happy thing that chemistry should be in a position of needing a 'something will always turn up' philosophy, only time and a great deal of work will prove-or disprove-such a contention.

Meanwhile, one might argue tentatively that the move towards interest in global structure, neighbour relationships and the problems of chemical identity touched on above are a proper, if delayed, response to the realisation that the truly basic problems of stereochemistry at the geometrical level were solved a very long time ago indeed by van't Hoff, Le Bel, Kekulé et al. and that a great deal of what has followed is elaboration rather than fundamental advance. Perhaps we shall know that something extraordinary has arrived when the authors of a radically new concept receive the kind of abuse which was heaped upon van't Hoff and Le Bel by chemists of the day, for daring to suggest that carbon atoms might combine in geometrically describable structures. But, if one's instincts are correct, this honour may well be reserved for someone in a field altogether remote from chemistry as we know it, and perhaps from physics too.

from our Molecular Physics Correspondent

### New light on old reflexes

THE voluntary muscles that move our limbs are full of sense organs, a fact in itself not surprising, although the use the central nervous system makes of the information they send it is perhaps more of a mystery than is the case for any other major group of sense organs in the body.

The most obvious manifestation of their action, the familiar knee jerk, obtained by striking the tendon below. the knee cap with a hammer, was described independently and almost simultaneously by Erb of Heidelberg and Westphal of Halle just on a century ago. In this reaction the tap to the tendon briefly stretches the muscle spindles (the most important of the sense organs in the muscle) and their discharge reflexly causes the muscle to twitch. Slower stretch of a human muscle that is already contracting, by forcible bending of the joint it acts on, also causes a reflex increase in contraction. Stretch reflexes of this general type were first described by Liddell and Sherrington in 1924 in animals rendered insentient by removing the cerebral hemispheres, whose muscles are unnaturally susceptible to stretch. The stretch reflex has long been a favourite object of research from the belief that it is an important and accessible element in the complex nervous mechanisms by which the muscle sense organs make the muscles, by some kind of feedback action, do what we ask of them. This belief is reinforced by the observation that stretch reflexes, as well as tendon jerks, are abnormal in neurological diseases such as stroke, in which the muscles conspicuously do not do what we ask of them.

The muscle spindles are the most elaborate sensory structures in the body other than the eyes and ears. Each consists of a bundle of fine modified muscle fibres with sense endings, sensitive to extension of these muscle fibres, wrapped around a central region. There are two different kinds of sense endings on the spindles, the primaries, connected to the central nervous system by fast conducting nerve fibres, and the secondaries, whose nerve fibres conduct at only a half or a third of the speed.

The latency of the knee jerk—the time from contact of the hammer with the tendon to the first sign of reflex activity in the muscle extending the knee—is about a sixtieth of a second, so short that the sense endings responsible must be the primaries with their fast nerve fibres. Even so, there is only just time for nerve impulses to get to the spinal cord and back. Until quite recently it was always supposed, following Sherrington's unhesitating identification of the knee jerk as a "fractional manifestation" of the stretch reflex, that the stretch reflex proper used the same sense endings and the same rapid spinal reflex pathway as the tendon jerk. This attractive but dangerous simplification is now under attack on two fronts.

First, P. B. C. Matthews discovered that the stretch reflex in the soleus (a muscle extending the ankle) of the cat was larger than the reflex contraction obtained by vibrating the tendon, a mode of stimulation that is believed on good grounds to excite the spindle primary endings powerfully and selectively. This strongly, if indirectly, suggests that the secondaries take part in the stretch reflex. There is no reason why they should not, for the stretch reflex has long latency components as compared with the tendon jerk. Now Kirkwood and Sears in this issue of *Nature* (page 242) present the crucial evidence that the nerve fibres from spindle secondaries, on entering the spinal cord, excite directly (monosynaptically) the motor nerve cells of the muscle in question (in these experiments a muscle of the rib cage). They have similar evidence for the secondary endings in cat soleus muscle (*J. Physiol, Lond.*, in the press). The involvement of the slow-conducting spindle secondaries in the stretch reflex of the decerebrate cat can now scarcely be doubted.

On the second front, Marsden, Merton and Morton (Nature, 238, 140; 1972; Lancet, i, 759; 1973) working on human subjects, found that in some muscles, for example the muscle that bends the top joint of the thumb, only long latency components are present in the stretch reflex. Following suggestions by Hammond and by Phillips, they argued that in such muscles the stretch reflex may not be spinal at all, but may travel over a pathway to the cerebral cortex and back. This theory may seem far-fetched at first sight, but trans-cortical reflexes from the limbs are not, in fact, a new idea in either physiology or neurology. A number of observations already fall into place on the transcortical theory of the stretch reflex, but much will have to be done to establish the theory firmly. In particular, there remains at present the possibility that the latency is long because only the spindle secondaries (to the exclusion of the primaries) take part in a spinal reflex. Results from muscles of the shoulder should throw light on this question.

These two new notions, that the secondary spindle endings take part in stretch reflexes and that some stretch reflexes may have a cortical reflex arc (notions, incidentally, by no means mutually incompatible), have a twofold significance. First, in clinical medicine, neurologists have long been puzzled that the stretch reflexes (measured as the resistance or 'tone' felt in a limb during passive movement) and the tendon jerks, which physiologists originally told them had the same mechanism, did not always go hand in hand when they altered in disease, and sometimes indeed changed in opposite directions. Now that there are at least two possible ways in which the mechanism of tendon jerks and stretch reflexes may differ, the way is open for a resolution of these problems and for a completely new approach to the whole nature of 'tone' in normal muscle and its alterations in spastic and other abnormal states.

More generally, any new information about the detailed mechanism of the stretch reflex is particularly welcome at this time when the work of Marsden et al. already referred to on the servo-like stretch-reflex-based responses of human muscles during voluntary movements has turned up several other new phenomena not foreshadowed in animal work on the stretch reflex and badly in need of explanation.

from a Correspondent

# An uphill route for climatic cycles?

Ir climate is the summation of weather over a period of time, then it makes sense to predict climatic changes in the same way as weather—that is by looking at present sequences of events and assuming that similar sequences will persist in the future. Such a method has been applied principally by Lamb and it is one of the concerns of his now rescued Climatic Research Unit (Nature, 251, 568 1974). But the detection of cycles alone does not indicate the causes of either regional or global climatic changes As realistic experiments are clearly impossible and

computer models cannot yet account for present climatic features, never mind their changes, the only practical approach is to define as closely as possible the nature and wavelength of climatic cycles and to compare them with any cyclical phenomenon that may alter climate. Lamb, for example, demonstrated that there was no strong correlation between climatic change and volcanic activity (Phil. Trans. R. Soc., A266, 425; 1970). If correlations can be established, causal relationships can be investigated bearing in mind that the two factors could be indirectly linked through some other variable.

But climatic records are of only limited range and difficult to quantify—Tacitus's description of the British climate in 75 BC as "objectionable, with frequent rains and mists, but no extremes of temperature" bears distinct resemblances to the British summer of 1974 AD, but cannot be taken to mean that we are at the same point of a climatic cycle! The only quantitative climatic measure for periods prior to meteorological measurements is that of temperature determined from the ratio of 18O to 8O now trapped in ice on Greenland and Antarctica and in skeletal remains preserved in sediments. This ratio can be measured with a high precision, but both situations raise difficulties about how the ratio should be interpreted as temperature. The snowfall over the Antarctic comprises a large amount of redeposited snow and the oxygen ratio in marine skeletal organisms is strongly affected by changes in salinity as well as by temperature. The oxygen ratios in ice sheets can be dated by short-lived isotopes or simply counting summer/winter layers—usually starting from the commencement of nuclear weapon testing which now provides an easily detectable marker horizon. But increasing compaction with recrystallisation tends to destroy the accuracy of counting and this method can only go back reliably for a few thousand years. Fossil foraminifera and other organisms can however be used to extend temperature determinations well into geological time and can be dated by standard geological methods, thereby allowing the detection of long-term cycles.

What about the factors that may alter climate? As Chappell says on page 199, there has been general acceptance that cyclical changes in the degree of solar radiation received at the Earth's surface occur because of long-term changes in the Earth's orbit. The periodicity of these changes was largely established by Milankovitch in 1938 and, assuming no changes in the solar radiation 'constant', it is possible to determine precisely the changes in the amount of insolation received at the Earth's surface. Calder, on page 216, re-evaluates Milankovitch's hypothesis in the light of revised insolation tables and concludes simply that these orbital perturbations are the first-order control on glaciation. But as Chappell points out, many critics have claimed that the radiation changes associated with these astronomical factors are very small and the direct effect of insolation may be insignificant compared with indirect factors. Chappell has previously shown many earlier correlations to be spurious, but now provides new and revised evidence for a degree of correlation between orbital perturbations, sea-level changes and palaeotemperatures for the last 250,000 years. His conclusion is also that

### More putative human tumour viruses

In this issue of Nature (page 247), McGrath, Grant, Soule, Glancy and Rich describe the release from a human breast carcinoma cell line (MCF-7) of virus particles that they believe may be human mammary tumour viruses. The particles have all the standard biophysical and biochemical properties of RNA tumour viruses, and virus-producing cells react specifically in indirect immunofluorescence tests with antiserum against murine mammary tumour virus. These findings support previous reports by Schlom, Axel, Spiegelman and their colleagues and by Moore's laboratory that virus particles related to murine mammary tumour viruses can be detected in human milk and in breast carcinomas. Unfortunately virus production from the MCF-7 cell line is rather poor and fickle, and this has hampered a more thorough analysis of the particles.

The sceptical reader will wonder whether the MCF-7 cells are really human cells and if so whether they are really derived from a breast carcinoma rather than a common laboratory cell, such as HeLa. On these points, McGrath et al. stand on reasonably firm ground, for in a previous publication (J. natn. Cancer Inst., 51, 1409; 1973) Soule, Fazquez, Long, Albert and Brennan characterised the MCF-7 cell line in some detail. MCF-7 cells are derived from cultures of a pleural effusion of a patient with metastatic mammary carcinoma. The subtetraploid cells seem to have a human chromosome pattern, although banding patterns have not been examined; they have a ribosomal RNA profile resembling that of human cells, and they carry human cell surface antigens and human glucose-6-phosphatase isozyme. MCF-7 cells show three features characteristic of mammary gland cells: cytoplasmic receptors for 17βoestradiol, synthesis of lactalbumin, and the formation in monolayer culture of epithelial 'domes' similar in morphology to those previously described by McGrath in murine mammary tumour cultures. Not all subclones of the MCF-7 cell line release virus particles. There

remains the possibility, of course, that although the cells seem to be genuine human mammary cancer cells, the virus may be a laboratory contaminant. But McGrath et al. feel that they can distinguish the MCF-7 particles from murine mammary tumour viruses, and there is no relationship at all with murine leukaemia virus.

In a paper published in the November 1 issue of *Nature* (252, 78), Lewis, Tannenberg, Smith and Schwartz suggest that an antigen detectable on lymphocyte membranes of systemic lupus erythematosis (SLE) patients is related to a C-type viral antigen. Antiserum prepared against the C-type virus produced by murine plasmacytoma SP 104 reacted in immunofluorescence tests to SLE lymphocyte membranes, but not to lymphocytes of normal subjects. Moreover, the serum of an SLE patient also reacted to SLE lymphocytes and this reactivity was specifically removed by absorption with gradient-purified SP 104 virus. Thus there seems to be a common antigen between SP 104 virus and human SLE cells.

SP '104 cells have a curious history and interesting properties. The plasmacytoma arose following inoculation of cell-free filtrates of canine SLE cells into CAF1 mice (Lewis et al., J. clin. Invest., 52, 1893; 1973). Yet the SP 104 virus stock includes a leukaemia virus containing murine gs-1 antigen. The SP 104 cells produce antibody against double-stranded DNA, as is found in SLE patients, and inoculation of SP 104 virus into normal mice or dogs induces the appearance of anti-nuclear antibodies. Thus the canine cell-free extracts and the SP 104 virus induce symptoms resembling SLE in recipient hosts. It is not known whether SP 104 virus contains canine as well as murine components; neither is it known whether the relation of SLE cell membrane antigens to viral antigens is specific to SP 104 virus alone. Nevertheless these studies do implicate a virus in the aeteiology of SLE, and they suggest that the human, canine and experimental murine forms are closely R. A. Weiss related.

astronomical factors are of prime importance, but the way in which world-wide climatic changes occur are very much more complex than indicated by Calder.

Such considerations are not merely of academic interest-they become vital as large-scale technology begins to alter the environment. What is the likely olimatic effect of diverting Soviet Arctic rivers southwards for irrigation projects? What would be the effect of a permanent ice-free channel for the movement of oil from Arctic Canada? What is the climatic effect of pollutants in the stratosphere? These questions will not be answered until a better dating system for the Quaternary enables the various cycles to be defined. Then the statistical validity of the many possible correlations can be tested and their causative relationship evaluated.

## Plants with talent for breeding or competing

from Peter D. Moore

POPULATION ecologists have made considerable use of the concept of r and Kselection, which was introduced by MacArthur and Wilson (The Theory of Island Biogeography, Princeton University Press; 1967). When intraspecific competition (and, therefore, densitydependent mortality) is low, natural selection operates chiefly through its density-independent component, selection. Taxa associated with such situations are said to be r selected. Conversely, when intraspecific competition and density-dependent mortality are high, K selection is operative. Theoretically, r selection should favour organisms which can breed rapidly, and K selection those which can most efficiently exploit a resource. Pianka (Am. Nat., 104, 592; 1970 and 106, 581; 1972) has pointed out that no organism is completely r selected or K selected, but lies at some point along a continuum between these extremes.

Investigations into selective pressures in populations of organisms have mainly concentrated upon animals, but Gadgil and Solbrig (Am. Nat., 106, 14; 1972) suggested that selective pressures took a similar form in populations of dandelions (Taraxacum officinale) in different types of grassland at Ann Arbor, Michigan. Since this species is extremely plastic in its morphology it was necessary to use isozyme patterns in leaf extracts to determine genetic biotypes. Four such variants were found, one (A) being associated with the most highly disturbed situations, another (D) being found in stable, undisturbed situations and the other two being intermediate. The series seemed to show a trend from r to k selection.

Solbrig and Simpson (J. Ecol., 62, 473; 1974) have now published some experimental data which support this suggestion. Taxa which have been subjected to r selection would be expected to expend a larger proportion of their energy resources in reproductive effort in order to exploit rapidly an unsaturated (low competition) environment. Energy expended per seed, however, need not be high because of the lack of intraspecific competition. Biotype A was found to produce an avovage of 25.3 seeds per plant with a mean seed weight of 0.32 mg; biotype D bore 8.2 seeds per plant with a mean seed weight of 0.44 mg. These extreme biotypes thus fulfil the theoretical requirements of r and K strategists in this respect. One would further expect a Kselected taxon to be a more effective competitor under high density conditions than an r-selected one. This was tested by growing the two biotypes both alone and in combination. When in pure culture there was no significant difference between the biotypes in terms of dry weight increase over 90 weeks. When grown together, however, type D always produced the heavier plants and had the lower mortality rate; it can therefore be regarded as the stronger competitor of the two.

These two extreme biotypes thus demonstrate adaptation apparently in response to differing pressures of r and K selection in their two sites. It is not possible, however, on the basis of these experiments, to determine whether these forms of selection are the most influential ones at work upon the dandelion genomes. Habitats in which r selection is operative are frequently subjected to severe edaphic and microclimatic stresses which could have an overriding selective influence on survival. K-selection situations on the other hand experience high levels of interspecific as well as intraspecific competition, which could call for rather different adaptive mechanisms. The apomictic nature and therefore the genetic homogeneity of dandelion biotypes will make them ideal material for the investigation of these further problems.

# Meteor rates, volcanoes and the solar cycle

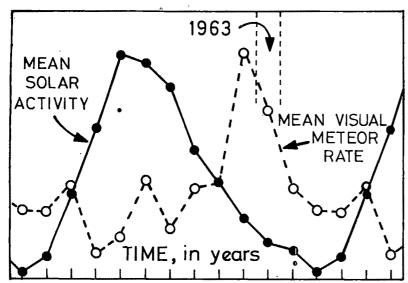

from David W. Hughes

A WORLD-WIDE increase in radar meteor echo rates occurred in 1963 and the cause of this has been puzzling scientists ever since. These echoes are obtained by reflecting short (100 µs) pulses of radiation (in the tens of MHz region) from the ionised trains produced in the

upper-atmosphere (at heights of 80 to 100 km) by incoming meteoroid particles. The number of echoes seen in 1963 was a factor of 1.5 to 2 greater than in previous and subsequent years and this increase was recorded in Christohurch, New Zealand<sup>1</sup>, Ottawa, Canada<sup>2</sup> and Onsala, Sweden<sup>3</sup>, so instrumental effects can be ruled out. The effect was periodic, in New Zealand occurring during the winter (June, July) and recurring on successive years with reduced magnitude. In the Northern Hemisphere the effect occurred initially in May 1963 but on following years recurred in the winter months, January-March. The Swedish data showed a rate increase for all echo duration. Canadian data however indicated that the anomalous increase was restricted to the smaller meteors. The rates were also proportionally higher throughout the day'.

Kennewell and Ellyett of Newcastle University, New South Wales have reconsidered the possible causes of the rate, increase in a recent article in Science (186, 355; 1974). They divide the possible causative agents into extraterrestrial and terrestrial.

Consider the extraterrestrial possibility first. There are no reasons why the influx of meteoroid dust to the Earth should not vary from year to year. For example certain meteor showers are distinctly periodic in their activity, the Leonids and Giacobinids being perfect examples. Showers are fed by the decay of the parent comet and it takes a considerable time for the new meteoroids to move around the comet orbit and form a complete, uniformly dense toroid of dust in space. The loop formation times of the Ouadrantid and Perseid meteor streams are for example 330 and 4,000 years respectively. The activity of streams which are young and not completely formed is expected to vary with the periodicity of the original comet (33 and 6 years respectively for the Leonids and Giacobinids) the dust still being closely grouped around the comet. A considerable proportion of the sporadic meteoroid background (~30%) is made up of minor streams and therefore the mean periodicity of these streams might be reflected in the total influx rate. But the 1963 increase extended over a period of some months which is incompatible with the period of activity of most meteor showers, usually less than a month. Also the fact that the recurring annual variations after 1963 were 6 months out of phase in opposite hemispheres cannot be explained. And the form of the monthly mean diurnal variation remained unchanged—this being something which would vary decidedly if a shower was active. Kennewell and Ellyett conclude that the rate in crease in 1963 was not

The mean visual meteor rate as a function of time throughout a solar cycle. The rate increases by a factor of two for the two years near solar minimum, being approximately constant over the rest of the cycle.

properties of the upper atmosphere change in 1963, resulting in the improved detection of meteors? The two

caused by an increased particle influx.

Is the cause terrestrial? Did the

main atmospheric parameters which affect meteoroid ablation are density and scale height. Now a uniform increase in atmospheric density down to meteor heights would cause no increase in the number of meteor echoes since the entire meteor population would simply rise in height. This would change the average range of the echoes. McIntosh<sup>4</sup> found a change in range of about 3 km in 160 km in 1963, a change which would have an insignificant effect on the rate. The initial radius of a meteor train varies as a function of height, also the reflected power from a train decreases exponentially with its radius. This produces a height ceiling effect, the echo height distribution being curtailed at the top. Smaller meteoroids which burn out at these great heights will be observed in greatly reduced numbers. But a simple increase in

observed rate remains the same. If the density gradient varies, as a result, for example, of a change in scale height the effect is more complex. First a larger train electron line density will result from a particular meteoroid thus allowing smaller meteoroids to come within the radar detection range. Second, a decrease in scale height will decrease the length of the train, making it more difficult to detect and will tend to cancel out the previous gain.

density just raises the height ceiling

with • the mean height, while the

Kennewell and Ellyett propose that the meteor rate increased because the scale height around 90 km changed after the massive injection of volcanic dust into the upper atmosphere by the eruption of Mount Agung on the island of Bali (8°S, 155°E) in March 1963. This dust was mainly concentrated at a height of 20 km but also formed a minor layer in the mesosphere where, by absorbing solar radiation, it led to the heating of the immediate atmosphere, a lowering of density in the region and a subsequent increase in the atmospheric density gradient higher up. The lag between the southern and northern hemisphere rate increases is thought simply to be due to dust transport times. Kennewell and Ellyett also show that total atmospheric dust content measurements made in Australia correlate with the meteor rate and that the biennial oscillation of the equatorial stratospheric winds could inject small particles into the mesosphere on alternate years and produce a twoyearly variation in meteor rates.

A cautionary note must however be sounded because 1963 is not the only year of excessive meteor rates. As Ethiopian rainfall, thunderstorm activity and the quality of claret vary with the solar cycle why shouldn't the meteor rate? This question was answered in the affirmative by the Czechoslovak astronomer Bumba in 1948 (Bull. Astr. Inst. Czech., 1, 93; 1949). He calculated, among other things, the mean annual rate of visual meteors during the period 1844-1933 as a function of position in the solar cycle and his results are shown in the figure. He also found that the ratio of bright to faint meteors and the mean observed geocentric velocity5 varies with the solar 11-year periodicity. There is an inverse correlation between solar activity and visual meteor rate, the rate maximising near solar minimum. This was also mentioned by Lindblad3 who found that the height of first appearances of meteors from a given shower remained around 110 km whereas the average end point rose from 85.2 km in 1956 to 96.0 km in 1963 -a change of 11 km. Lindblad also

found the 1953 rate considerably higher than the average.

If the increase around 1963 is just a solar cycle effect (a deduction supported by the work of Bumba and Lindblad) and not a one-off affair caused by a volcanic explosion (and it can be seen from the figure that 1963 coincides exactly with visual rate increases seen between 1844 and 1933) then similar increases should be found at other times of solar minimum, for example during 1972-73. So now is an excellent time for visual observers to peruse their records to see if this increase occurred. Also the experts in meteor ablation theory and upper atmosphere physics should try and work out why the solar cycleinduced variation in atmospheric scale height has such an effect on observed meteor rates. They could also investigate whether some unknown factor affecting meteor physics and ion chemistry varies with an 11-year periodicity. As the meteor rates are proportionally higher during the day perhaps the decrease in solar X-ray and ultraviole flux at solar minimum have an effect.

### **Pinned** superfluid vortex

from P. V. E. McClintock

A QUANTISED vortex line stretched between definite pinning sites in superfluid helium has apparently been observed for the first time by Jost, Bogatin and Weaver of the Massachusetts Institute of Technology (Physics Letters. 49A, 147; 1974).

Liquid helium four below its so-called lambda transition temperature at 2 K behaves in many ways as though it were a mixture of two distinct fluids: a normal component which has similar properties to ordinary liquids; and a superfluid component which, having zero viscosity, is able to flow effortlessly through channels of vanishingly small dimensions and is thus responsible for the well known and very peculiar properties exhibited by the liquid.

One of the oddest features of the superfluid component it is that it cannot rotate in a conventional manner. There is excellent theoretical and experimental evidence showing that, if a container of superfluid helium is slowly rotated, the liquid remains at rest with respect, presumably, to the fixed stars, no matter how long the experiment is continued. If the angular velocity of the container is further increased, however, then it may become energetically favourable for one or more vortex lines to appear in the liquid. Each of these consists of a narrow core, oriented parallel to the container's axis of rotation, and around which the helium flows with a tangential velocity which is inversely proportional to the distance r from the core. The strength, known as the circulation, of each vortex is quantised in units of h/mwhere h is Planck's constant and m the mass of a helium atom but, so far, only singly quantised vortices have ever been detected.

Arguments based on minimising the total energy suggest that a single vortex line in a smooth container will lie along the axis of rotation, that two vortices will circle around each other under influence of their mutual flow fields, and that larger numbers of vortices will form a hexagonal lattice rotating with the container. But the recent elegant photographic experiments of Packard and Sanders (Phys. Rev. Lett., 33, 280; 1974) have shown that this does not seem to be the case in practice: the vortex cores seemed to be arranged in no definite pattern and indeed to wander aimlessly relative to the container while still presumably remaining parallel to its rotational axis.

The MIT group employed a container with a pair of definite pinning centres, designed to detect the appearance of a single vortex. The helium was contained in a 2.5 mm diameter cylinder at each end of which, positioned on the axis, was a needle, the two points being separated by about 5 mm. There were two reasons why it was expected that the first vortex would form between the needle points: first, even in a flat-ended container, a single vortex minimises its energy by being on the axis of rotation; and, second, by spanning the space between the needles, the vortex could be shorter, and thus of lower energy, than in any other feasible position. To detect the formation of a vortex line, one of the needles

was used as a field emitter, injecting electrons into the liquid, while the other acted as a collecting electrole. Because vortex lines are able to trap and hold electrons, it was hoped that there would be a sudden change in the collector current when the vortex appeared.

As the rotational speed of the chamber was gradually increased from zero, a discontinuous decrease in the collector current was indeed observed, and it occurred at approximately the expected angular velocity. Although the mechanism responsible for the fall in collector current is still not understood in detail, the authors ascribe the phenomenon to the formation of a singly quantised vortex line strung between the two needles. If they are right, then it will be the first time that a pinned vortex, long a familiar concept in connection with superconductors, has been observed in superfluid helium.

A particularly interesting suggestion by the MIT group is the possibility of using the same apparatus to search for a vortex line having two or more quanta of circulation. They argue that, if the separation of the needles is considerably less than the length of the chamber then, as the rotational speed is increased, it must be energetically preferable to add more quanta of circulation to the existing pinned vortex rather than creating further singly quantised lines which would have to span the whole length of the cylinder. Their preliminary attempts to detect such a double-strength vortex have been unsuccessful. This is perhaps because of the randomly orientated tangles of vortex lines which are believed to be generated by electrons in the large electric field close to a field emitter and which would be likely to interfere with the stability of the main. rotationally created, vortex. If this effect can be suppressed, however, perhaps by conducting the experiment under pressure when it is known that electrons have much less tendency to create vortex lines, some interesting new phenomena may be anticipated.

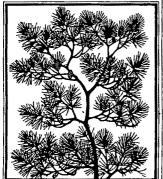

## On the trail of epidemic hepatitis

from Arie J. Zuckerman

INFECTIOUS or epidemic hepatitis, now referred to as hepatitis type A, remains a major public health problem, occurring endemically in all parts of the world with frequent reports of small and large epidemics. Spread is usually by person to person contact and major outbreaks result most frequently from the faecal contamination of water and food. Subclinical cases are common: the disease has in general a low mortality but patients may at times be incapacitated for many weeks or months. Further general information on transmission experiments to human volunteers and studies in non-human primates may be found in a recent WHO report (Viral Hepatitis: Report of a WHO Scientific Group; Techn. Rep. Ser., 512; 1973).

The discovery of the association between an antigen found in blood and hepatitis type B (serum hepatitis) has prompted efforts to find a similar antigenic marker in patients with hepatitis type A. To date, a specific serum antigen has not been found but examination by immune electron microscopy of faecal extracts prepared from patients with acute hepatitis A yielded interesting results. An antigen was detected by immunodiffusion in faecal extracts from about 50% of patients admitted to hospital in Australia with hepatitis A and in only 2% of control patients (Ferris et al., Lancet, ii, 243; 1970). Antigenic activity was associated with two types of particles measuring 15-25 nm and 40-45 nm in diameter. Animal antisera to this faecal antigen yielded encouraging results but also a number of non-specific reactions, and studies are currently in progress with antisera with improved specificity.

In December 1973, virus-like particles measuring 27 nm in diameter were demonstrated by immune electron microscopy in faecal extracts obtained from 2 out of 4 adult volunteers who were infected by injection or by

Painted panels from the ceiling of the Natural History Museum, London, According to The British Architect and Northern Engineer of June 1878 "the chief idea . . . is that of growth". Left to right: Scots pine Pinus sylvestris; peach Amygdalus persica; cacao Theobroma cacao; English oak Quercus robur.

mouth with the MS-1 strain of hepatitis A virus (Feinstone and colleagues, Science, 182, 1026; 1973). The particles were heavily coated with antibody and they were aggregated by convalescent serum. These particles were not found in faecal specimens before infection, they were only detected at the onset of clinical symptoms, and pre-illness sera did not contain antibodies to the viruslike particles. Faecal filtrates containing these 27 nm virus-like structures were used to examine by electron microscopy several groups of sera for the presence of antibody. All 6 volunteers previously infected with hepatitis A developed serological evidence of infection as judged by aggregation and antibody coating of the 27 nm particles. Similar results were obtained with sera from patients with a number of naturally occurring outbreaks of hepatitis A. Other studies have shown that the buoyant density of the faecal particles in caesium chloride was 1.41 g ml-1 and together with the morphological appearance and known resistance to ether, acid and heaf the data suggest that this particle is a parvovirus (Feinstone and associates, J. Virol., 13, 1412; 1974). Morphologically and antigenically similar particles were also demonstrated in faeces from patients from at least one geographically separated outbreak of hepatitis A (J. Maynard and colleagues, personal communication). The particles identified in Arizona banded, however, in two peaks in caesium chloride at 1.29-1.33 and at 1.39 g ml<sup>-1</sup>. Preliminary data from experimental transmission to marmosets and susceptible chimpanzees have also demonstrated a close association between the faecal particles and hepatitis A.

On the other hand, it is generally recognised that faeces contain a multitude of bacterial, bacteriophage, viral and other particulate antigens. Almeida and her colleagues (Lancet, ii, 748; 1974) examined by immune electron microscopy and by immunodiffusion faecal, extracts and acute and convalescent sera from an outbreak of hepatitis A. Faecal extracts reacted with convalescent sera contained frequent distinctive aggregates having the appearance associated with immune complexes. But particles resembling bacteriophage, particles resembling togavirus and a range of spherical particles were all present in distinct immune complex form. Serological analysis by gel diffusion showed seroconversion to more than one antigen present in the faeces, and seroconversion was also detected to antigens present in a number of control faecal extracts. It was also pointed out that it is known that antibody titres to bacterial, viral and dietary antigens are increased in patients with acute and chronic liver disease and this may account for the multiplicity of immune reactions in viral hepatitis.

The latest results reported by Almeida and colleagues (Lancet, ii, 1083; 1974) after the examination of faecal extracts from one of the infected adult volunteers tested by Feinstone and associates (loc. cit.) confirmed the presence of the 27 nm particles, but at least two small cubic virus-like particles were found in addition. Using the technique of immune electron microscopy in London, extracts of faeces obtained 33 days after infection with the MS-1 strain of hepatitis A were found to contain virus-like structures which varied in their size. Both 'full' and 'empty' particles measuring 22 nm, 27 nm and 30 nm in diameter could be distinguished and they seemed to have a cubic symmetry. Each of these viruslike structures was clearly coated with antibody and the particles were aggregated by convalescent but not by acute serum from hepatitis type A. The fact that this material has also induced hepatitis in 2 out of 6 marmosets suggests that hepatitis A virus is indeed present. But the precise relationship to the disease of the three virus-like particles now described remains uncertain.

The success of immune electron microscopy in elucidating the complex antigenic reactivities of hepatitis B virus may blaze a trail for what seems to be an equally puzzling array of particles present in the faeces, and perhaps the serum, of patients with hepatitis A infection.

## Eclogite model of upper mantle

from Peter J. Smith

THE view that the Earth's upper mantle might be eclogitic in composition was put forward over 60 years ago by Fermor (Rec. Geol. Surv. India, 43, 41; 1913), although since then it has received comparatively little support. According to Green and Ringwood (Phys. Earth Planet, Interiors, 3, 359; 1970), for example, "the weight of geological and geophysical evidence on upper mantle composition favours an overall peridotitic composition", and the arguments against an eclogitic composition were given by Ringwood and Green (Tectonophysics, 3, 383; 1966). During the past decade, Green and Ringwood (see, for example, Earth planet. Sci. Lett., 3, 151; 1967) have given particular attention instead to their "pyrolite" composition, although the validity of this system is by no means universally accepted.

Interest in the eclogite model began

to revive in 1970 when Press (Phys. Earth Planet. Interiors, 3, 3; 1970) used a Monte Carlo procedure to derive a series of Earth models consistent with geophysical data. Specifically, he found that of about 50 acceptable density models, about 30 required densities of at least 3.6 g cm<sup>-1</sup> somewhere in the upper mantle. Both Press and Birch (Phys. Earth Planet. Interiors, 3, 178; 1970) interpreted these high densities to favour almost exclusively an eclogitic composition for the upper mantle, and thus for the low velocity zone, although Birch did add that an iron-rich olivine upper mantle might still be possible. At this point, however, it became clear that any detailed discussion of an eclogitic upper mantle would be seriously hampered by the relative lack of experimental data on eclogites, in particular on their elastic properties.

Some results on the seismic velocities in eclogites have now been provided by Rao et al. (Earth planet. Sci. Lett., 23, 15; 1974), and they show just how involved the situation is. Eclogites from India, Czechoslovakia and Japan all have comparable garnet compositions and mean atomic weights, but there are significant differences in P wave velocities and velocity-pressure gradients. Velocities at 4 kbar, for example, range from 7.43 km s<sup>-1</sup> for the Indian eclogites, through 8.05 km s<sup>-1</sup> for those from Japan, to 8.35 km s<sup>-1</sup> for the Czechoslovakian samples. For the same location order, average velocitypressure gradients are, respectively, 0.08, 0.058 and 0.036 km s<sup>-1</sup> kbar<sup>-1</sup>.

The reason for these variations is that the apparent distribution constant (K) of Fe-Mg between coexisting garnets and pyroxenes varies from one set of eclogites to the other, indicating that the conditions of temperature and pressure under which they formed were different. In fact, Rao and his colleagues are able to demonstrate a linear relationship between P wave velocity and K. But details apart, the general point to be made is that if the eclogite model is now to be considered seriously, much more experimental work will be required to elucidate the complexities of eclogite systems—as much, perhaps, as has been done on the more popular pyrolite systems.

#### Erratum

In the article "The Linear Differentiation of Chromosomes" (Nature, 252, 95; 1974) the statement was made that "the many current attempts to explain banding reflect our lack of knowledge of how 1 cm of DNA can be packed with protein into a 1 mm transverse band". 1 cm of DNA is in fact packed into a 1  $\mu$ m transverse band.

### Congenitally abnormal vision in Siamese cats

R. W. Guillery, V. A Casagrande & M. D. Oberdorfer

In albino mammals, the absence of pigmentation in the eye is associated with abnormalities of the visual pathway and these result in a scrambled input to the visual centres of the brain. Recent research on Siamese cats, in which more than one pattern of abnormality has been found, shows that there are several ways in which the cortex can deal with the abnormal input, and is beginning to define the rules according to which the cortex selects its inputs.

THE sensory centres of the brain carry an orderly representation of the environment as shown by many topographically organised sensory 'maps'. While it seems likely that such orderly representations are essential for the proper functioning of sensory mechanisms, it is difficult to test this rather general view, because one cannot easily challenge sensory mechanisms by providing them with a scrambled input. Recently, however, the discovery that some mammals have congenitally abnormal visual pathways has provided an opportunity for testing how cerebral mechanisms can respond to disordered inputs, and studies of the abnormal pathways have begun to show some of the rules on the basis of which cerebral representations of the outside world can be established.

Mammals with abnormally low amounts of pigment in the retinal pigment epithelium have abnormal pathways linking the eyes to the brain<sup>1-8</sup>. Generally, the abnormality involves nerve fibres that arise in the temporal parts of the retina. Whereas in normal animals all such fibres would pass to the cerebral hemispheres without crossing (Fig. 1), in the abnormal animals some of the temporal fibres cross the midline (Fig. 2a).

#### Retino-geniculate connections in Siamese cats

The precise pattern of the abnormal projection has been worked out in most detail for the lateral geniculate nucleus of Siamese cats<sup>9-11</sup>, and Fig. 2(a) summarises the results obtained by anatomical and electrophysiological methods<sup>9</sup>. The basic pattern of the abnormality is simple. Some of the retino-geniculate axons go to the wrong side of the brain, but the geniculate locus of all axon terminals relates to the retinal locus of their cells of origin in a normal mapping. Thus, in Fig. 2a, segments 10\*, 11\* and 12\* of the left retina are shown passing to the right lateral geniculate nucleus instead of the left. Within the right nucleus they terminate in the appropriate cell layers (shown as layer A1 in Fig. 2) and the axons that arise in segment 10\* end medially, while those arising in segment 12\* end laterally, as is normal. It can be seen that segments 5\*, 6\* and 7\* from the left eye, which would normally map opposite segments 5+, 6+ and 7+ from the right eye, in Siamese cats map opposite segments 12\*, 11\* and 10\*, respectively, from the left eye.

The distribution of the abnormal fibres does not vary greatly in Siamese cats. There is always a lateral, normally connected segment of lamina A1 (3<sup>+</sup> and 4<sup>+</sup> in Fig. 2a, the 'lateral normal segment') and next to it is a large

abnormally connected segment, the 'lateral abnormal segment'. The border between the two (arrow in Fig. 2a) generally receives from retina that lies 15° to 20° from the line of decussation. Most of the cats that have been examined also show a small 'medial normal segment' of lamina A1 (8<sup>+</sup> in Fig. 2a), but the size of this segment varies somewhat between animals, and it may possibly not occur at all in some Siamese cats (see below).

Fig. 2a shows that the lateral geniculate nucleus receives an abnormal representation of the visual field. It seems as though there are geniculate mechanisms that sort axons in terms of retinal topographies, but that there are no mechanisms for correcting the nonsense appearing in terms of orderly visual field representations. We shall see that this is in striking contrast to the situation in the visual cortex.

There are three major consequences of the simple retinogeniculate misrouting, and we shall refer to them as a 'disruption', an 'inversion' and a 'non-correspondence'. The first term refers only to the fact that within one geniculate layer the visual field segments are represented in an interrupted manner. An inversion occurs when a portion of the visual field representation is a reversal of the normal, so that one finds an ascending sequence in one part of layer A1 (10\*, 11\*, 12\* in Fig. 2a) and descending sequence in another portion of the same layer (4+, 3+). An inversion is a special case of a disruption, and each involves only a single geniculate layer. A non-correspondence, which is any mismatching of two adjacent. layers, is necessarily an interlaminar phenomenon. It is possible to produce a non-correspondence without a disruption and to produce a disruption without a reversal, and thus, it is useful to consider the three as distinct abnormalities.

### The geniculo-cortical pathways in Siamese cats

Figure 1 shows that in a normal cat the visual cortex receives an orderly, binocular representation of the contralateral visual field. Hubel and Wiesel<sup>12</sup> have established that most neurones in the visual cortex receive inputs from both sets of geniculate layers and can be activated through either eye. Such a balanced, binocular geniculo-cortical projection would clearly lead to serious problems in Siamese cats, since cortical activity would provide an ambiguous representation of the environment. Figure 2b shows that if the geniculo-cortical pathways in Siamese cats were arranged as in normal cats, some cortical celproups would be activated by two quite different parts of the visual field. Further, a movement from left to right across the visual field would be represented ambiguously

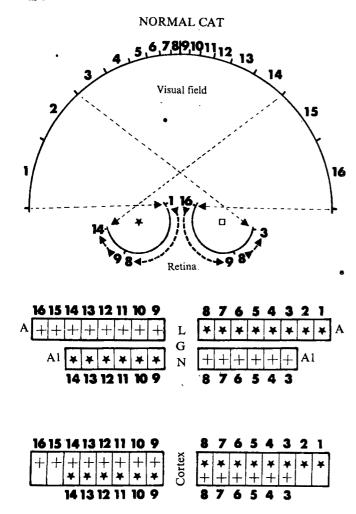

Fig. 1 The normal retino-geniculo-cortical projections in a cat. The representations of the visual field within the visual centres are shown as numbered sequences. Those coming through the right eye are marked by plus signs, and those coming through the left eye by stars.

within the cortex, being in one direction for segments 5\*, 6\* and 7\*, and in the opposite direction for segments 10\*, 11\* and 12\*.

Let us first consider the non-correspondence produced by the abnormality in terms of information available about normal cats. The visual cortex of normal cats can be made to receive noncorrespondent inputs by quite simple manipulations. When normal cats are reared with a surgically induced squint, the inputs to adjacent geniculate layers are made non-correspondent and single cortical cells no longer receive binocularly matching stimuli<sup>13</sup>. The geniculocortical pathway in such cats becomes modified so that individual cortical cells receive a monocular input. Cells receiving from each eye tend to be grouped together in distinct cortical columns. Within the cortex, instead of a single binocular representation of the visual field, two separate monocular representations are formed, and these are arranged as a mosaic of interdigitating monocular columns. A similar result has been obtained in kittens reared with alternating occlusion of the eyes<sup>13</sup>. Again, cortical cells were exposed either to right eye or left eye stimulation; since they were never exposed to correspondent binocular inputs, no binocular cortical columns were formed.

On the basis of these observations on non-correspondent geniculate inputs one might expect a similar result in Siamese cats. Considering first a Siamese cat with no strabismus, one might expect the situation illustrated in Fig. 2b, which shows a hypothetical, not an actual cortical

pattern. Binocular columns are shown in the cortical regions that receive from the normal segments of the lateral geniculate nucleus (3 4, 8 in Fig. 2b) and a mosaic of monocular columns is shown for the abnormal segments (5\*, 6\*, 7\*, 10\*, 11\*, 12\*). A cat with a significant strabismus, and this is quite common in Siamese cats, might be expected to show two independent sets of monocular columns for the whole visual field representation. The Siamese cats that have been studied so far, however, have shown a strikingly different cortical pattern.

### Cortical suppression of the temporal visual field

The pattern of neuronal activity that we have found in the visual cortex of most Siamese cats<sup>14</sup> is shown schematically in Fig. 3a. The input coming through lamina A from the contralateral retina (1\* to 8\*) appears to be quite normal, but it is difficult to record much cortical activity corresponding to an input from lamina A1. Segments 8<sup>+</sup>, 10\* to 12\*, 4<sup>+</sup> and 3<sup>+</sup> are, therefore, shown as thinner figures and smaller symbols in Fig. 3a. It seems that the visual cortex in these animals is looking at the whole visual field through the A laminae on each side, and that all of the inputs coming through the A1 laminae, which contain an inversion, are suppressed.

The cortical activity suggests that these Siamese cats have a normal field of view when they are using both eyes, but when they are only using one eye the effective field of view is limited to the parts of the visual field seen by the nasal retina. That is, the cat sees on the side of the open eye, but does not see across the midline at all.

Elekessy et al.<sup>15</sup> have used behavioural methods to study the visual fields of Siamese cats. They showed, independently, almost the exact limitation of the visual fields that our results led us to expect. Whereas normal cats have about 135° of visual field in each eye<sup>16,17</sup> (Fig. 1), their Siamese cats had only about 90° of visual field extending from close to the midline to the temporal periphery (1 to 8 for the left eye in Fig. 1).

It is clear that these Siamese cats do not develop a binocular mosaic of independent monocular inputs. Instead, there is massive suppression of the inverted segment (10\*, 11\*, 12\*, in Fig. 3a) and even the segments of the visual projection that are normal (3\*, 4\*, 8\*, in Fig. 3a) do not establish a demonstrable, cortical field. The suppression in these normally connected segments shows that lateral interaction must play a part in the development of the geniculo-cortical pathways. Segments 3\* and 4\* in Figs

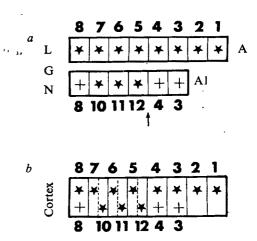

Fig. 2 The abnormal geniculo-cortical pathway to the right hemisphere in Siamese cats. a, Abnormal representation of the visual fields found in the right lateral geniculate nucleus of Siamese cats. b, Cortical patterns that might be expected if the geniculo-cortical pathways were normal (see

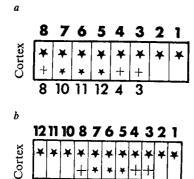

Fig. 3 a, Cortical representations of the visual field found in 'Midwestern' Siamese cats. b, Cortical representations of the visual field found in 'Boston' Siamese cats. The lighter numbers and smaller symbols represent a weak cortical input.

2 and 3a can only be regarded as abnormal because they form a part of a sequence that contains an inversion. It seems that the cortex does not accept inverted representations of the visual field, even though it can accept non-correspondent ones.

### Correction of the inverted representation

While the cortical pattern shown in Fig. 3a is found in some Siamese cats, other Siamese cats show a second pattern. This has been demonstrated electrophysiologically by Hubel and Wiesel<sup>11</sup> and by our own anatomical evidence<sup>14</sup>. The most striking feature of this second pattern is the reversal of the geniculo-cortical projection of segments 10\*, 11\* and 12\* (see upper row in Fig. 3b) and the insertion of these segments into cortex that normally receives from close to the zero vertical meridian. The cortical input from these abnormal geniculate segments to the expected cortical locus (opposite 5\*, 6\* and 7\*) is correspondingly reduced. The total amount of the visual cortex is not increased in these cats, but about 135° of visual field is represented in the cortex instead of the normal 90°.

The sequence of the visual field representations shown in bold figures is normal, except for the hiatus between 8 and 10, and the size of this hiatus on the right corresponds to the size of the medial normal geniculate segment on the left (9\* and 9\*). Thus, the modified geniculocortical projection in these cats has corrected the reversal, but appears to have left a small disruption. Any cat in which the medial normal segment was small or absent would show a virtually complete recreation of the normal sequence of visual field segments, and it is possible that the size of the medial normal segment is critical in determining whether the cortical pattern shown in Fig. 3a or that shown in Fig. 3b will be formed. If normal cortical function depends upon an uninterrupted sequential ordering of the visual field representations in the cortex, a cat with a large medial normal segment, which could establish a normal sequence only by suppressing the input from layer A1, would have to use the solution shown in Fig. 3a, while a cat with a small medial normal segment might use the more elegant solution illustrated by Fig. 3b.

We have called these two types of cortical pattern the Midwestern (Fig. 3a) and the Boston pattern (Fig. 3b)<sup>14</sup>. We do not know whether the formation of one or the other is related to the size of the medial normal segment. In fact, we know nothing of the mechanisms controlling the development of these pathways. The problem has been discussed by Gaze and Keating<sup>18</sup>, and it is relevant that the solution they propose for the formation of the Boston pattern also assumes an absence of the medial normal segment.

No one has yet tested the visual fields of a Boston cat. From the cortical records that have been obtained", however, one can reasonably expect that Boston cats have a normal 135° field of view. The visual field test may therefore prove to be useful for further studies of the Siamese abnormality, since it is relatively simple and can be made without any injury to the cat. Some such test for distinguishing Boston from Midwestern cats will be needed for studies of the inheritance patterns of the abnormalities and for further developmental studies.

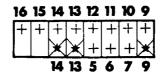

### Effects of monocular deprivation in Siamese cats

The effect of the inversion in the lateral geniculate nucleus can be tested by raising Siamese cats with one eye sutured. In Midwestern cats monocular deprivation will have the effect shown by crosses in Fig. 4. On both sides the inversion of the visual field representation within lamina A1 will be abolished. Further, the parts of lamina A1 receiving visual input will form a continuous, though partial representation of the visual field on one side (5<sup>+</sup>, 6<sup>+</sup>, 7<sup>+</sup>), and a disrupted representation on the other (3<sup>+</sup>, 4<sup>+</sup>, 8<sup>+</sup>). This disruption should be distinguished from the type of disruption that occurs, for example, in Fig. 3bbetween segments 8 and 10. In Fig. 3b there are no geniculate segments between 8 and 10, and we regard this as a 'strong' disruption. In Fig. 4 the amount of geniculate nucleus between segments 4 and 8 is appropriate for the intervening visual field segments, and we call this a 'weak' disruption.

In normal cats monocular deprivation upsets a balanced binocular competition and leads to a dramatic reduction in the cortical input from the deprived eye<sup>17,19,20</sup>. In Siamese cats monocular deprivation will upset this balance in geniculate segments 3, 4, 8 (Fig. 2a), but will not affect it in the rest of the nucleus.

Three Siamese cats that were raised with one eye sutured have been studied electrophysiologically<sup>14</sup>. All three cats showed a Midwestern pattern, but in each, stimulation of the temporal retina activated cortical cells more effectively than in normal Siamese cats: although the input from lamina A was still dominant throughout the cortex in these three kittens, all parts of lamina A1, except for the normal deprived segments (9\*, 13\*, 14\*) showed this increased effectiveness. These changes occurred within the abnormal segments even though the balance of the translaminar interaction had not been altered at all: it was the sequence of the representation within lamina A1 itself that had been altered by the deprivation.

More recently we have raised three Siamese kittens with one eye sutured from postnatal day 9 until they were 6-9 months old. We then tested their visual fields behaviourally, using essentially the same methods as Elekessy et al. (see ref. 17 for details). Visual responses were tested along guidelines at 15° intervals and we found that all three kittens had about 135° of visual field for the nondeprived eye (Table 1 and Fig. 5). That is, the visual fields of the nondeprived eye were like those of a normal cat, as would be expected from our earlier electrophysiological observations. Suturing one eye had increased the effective visual field of the other.

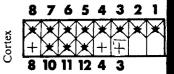

Fig. 4 Schema to show the expected effects of monocular visual deprivation in a Midwestern Siamese cat. Segments that are deprived by suturing the left eye shortly after birth are shown by large crosses.

Table 1 Test scores for	guidelines at 15° intervals,	(% of correct responses	s: 50 trials for each score)*

<sup>\*</sup> Final scores are corrected as follows: Where blank scores (B) were greater than guideline scores (G) (see ref. 17 for definition) the corrected score was G-B 100-B

We regard all three kittens as Midwestern: the retrograde degeneration produced by a cortical lesion has demonstrated this for one of the kittens (see ref. 14 for method). The other two are still living, but since the overwhelming majority of the cats we have obtained locally have been Midwestern cats, and since the two parents (OM and OF) and one unrelated control (668) have shown a limitation of the monocular fields that is not normal (Table 1 and Fig. 5), the conclusion that we were dealing with Midwestern cats seems justified, even though there is some spread of visual responses across the midline in the two parents. This spread may represent uncontrolled eye movements or may, perhaps, indicate some vision in the temporal retina. Since the amount of the visual sparing is distinctly less than would be expected in Boston cats and since there are no grounds for expecting such a limited sparing in Midwestern cats, we favour the former view.

It remains to be pointed out that in these three kittens we were testing cortical, not tectal functions: it is known that the tectal visual fields demonstrable behaviourally do not cross the midline (ref. 16 and M. S. Sherman, unpublished), and the behavioural results matched the activity recorded in cortical nerve cells of comparable cats<sup>14</sup>.

The visual cortex in the monocularly deprived Siamese cats was, therefore, able to produce accurate control of movement in spite of the fact that within one area of cortex two different parts of the visual field were represented in reverse order (10<sup>+</sup>, 11<sup>+</sup>, 12<sup>+</sup>; 7<sup>+</sup>, 6<sup>+</sup>, 5<sup>+</sup>). The non-correspondence was dealt with successfully, even though the two representations were opposed in direction, and presumably a mosaic of alternating monocular columns was established in the cortex. The critical difference between the normal and the monocularly deprived Siamese cats is the lack of any inversion within a single geniculate layer. Thus, the cortex must monitor its geniculate inputs in terms of the sequences coming from individual layers. Non-correspondences can be accepted, even when they involve complete reversals, but inversions within one geniculate layer are unacceptable. The weak form of the disruption occurring between segments 8+ and 5<sup>+</sup> in Fig. 4 seems not to prevent the formation of cortical connections, but we have seen that there is some indirect evidence that the strong form of the disruption occurring between segments 8\* and 10\* in Fig. 3b may be unacceptable.

When the tests summarised above were completed, the sutured eye was opened and the testing continued with this eye only. To date, we have found no signs of any vision in the deprived eye. This is in marked contrast to a normal

cat: when a normal cat is raised with the left eye sutured, the visual functions are spared in the right monocular geniculo-cortical segments (1 and 2 in Fig. 1) within which the deprived pathway has not had to compete with the normally innervated one. Even though segments 1 to 4 are

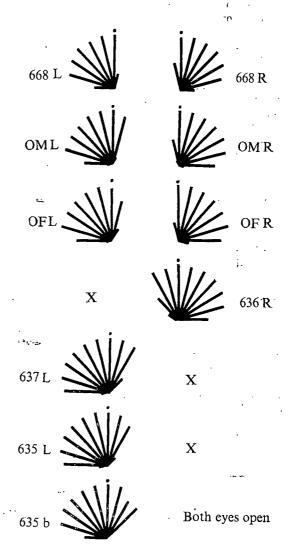

Fig. 5 Schematic representation of corrected guideline scores from table 1. The midline is indicated by a dot. X shows the sutured eye. 635b shows visual fields in a cat that was raised with the right eye sutured and that was subsequently tested with both eyes open.

connected into the retinocortical pathways in the same way in normal and Siamese cats, segments 1 and 2 react to lid suture in quite different ways in the two sorts of cat.

This is a puzzling observation and there is, at present, no direct evidence to explain it. We suggest that the difference must be produced by the abnormality in segments 10\*, 11\* and 12\* (Fig. 4). If an adult cat is no longer able to establish a mosaic of alternating monocular columns, then the cortex of our monocularly deprived cats had no way to separate the lamina A inputs from the lamina A1 inputs when the deprived eye was opened. The total new input pattern contained an inversion and this is why the whole sequence was suppressed at cortical levels.

It would seem then that the development of cortical 'maps' depends upon the coherence of the sensory representation that can be established in the cortex. A noncorrespondence can be turned into two independent coherent cortical representations in an infant, but probably not in an adult. Incoherence, whether produced by a strong disruption, by an inversion, or by a fusion of non-correspondent inputs, leads to blocked development of a cortical representation. In contrast to this, geniculate representations, even when they are incoherent in terms of the visual field, are successfully established on the basis of retinal locus.

We have shown that the abnormality found in albino mammals can be used to study the mechanisms by which orderly visual field representations may be established. So far we have only considered problems that arise in the geniculo-striate system of Siamese cats. Other parts of the visual pathway are also abnormal in these cats 10,21,22, however, and it may prove that they develop according to different rules. Further, the precise pattern of the abnormality differs in other species. Albino ferrets show a very large abnormality and have practically no uncrossed retinogeniculate axons'. Abnormal pathways have been found in several genotypes of mink<sup>8</sup> and the size of the abnormality, which is related to the amount of pigment in the retina, varies considerably. Thus there is a variety of models on which one can test hypotheses about the visual pathways.

So far our studies of Siamese cats have shown that in at least one sensory system the cortex monitors the sequence of its sensory inputs, and that there are definable rules according to which disrupted inputs can be rejected.

We thank Dr J. H. Kaas who collaborated in many experiments and Mrs E. Langer and Mrs B. Yelk who helped with the preparation of materials. The work was supported by grants from the Public Health Service, National Institutes of Health.

### Relationships between sealevels, <sup>18</sup>O variations and orbital perturbations, during the past 250,000 years

J. Chappell

Department of Geography, School of General Studies, Australian National University, Box 4, PO, Canberra, Australia 2600

Sealevel changes over the past 250,000 yr, determined from dated coral reefs on rising islands, are synchronous with precessional changes in solar radiation when orbital eccentricity is large. Oxygen isotope variations in deepsea cores correspond in timing but not in amplitude, reflecting changing isotopic composition of Pleistocene icecaps.

WORLD climates during Quaternary times were influenced by two primary factors. First, there have been variations in the geographical and seasonal distribution of solar radiation, which resulted from perturbations in the Earth's orbital motion. Second, there was the role of the oceans in transferring heat from low to high latitudes, thus influencing strongly the periodic growth of the Laurentide and Fennoscandian Pleistocene icecaps.

The analysis by Milankovitch<sup>1</sup> of orbital perturbations

and variations of radiation has been supported by several workers<sup>2-4</sup>. This astronomical theory of climatic change has, however, been criticised<sup>5-8</sup>, principally because changes of radiation are themselves very much smaller in magnitude than the observed Quaternary temperature changes. Advocates of the astronomical theory suggest that icecap growth and decay may both be self-amplifying processes, under certain conditions, and that triggering from one state to the other is effected by the changing distribution of solar radiation<sup>8,10</sup>. The case for the astronomical theory rests essentially on a correspondence between insolation curves and well dated records of Quaternary temperatures or ice volumes. Until recently, oxygen isotope and micropalaeontologic studies of deep-sea cores provided the best basis for such arguments. The statistical methods for correlation between the core records and insolation curves have, however, been disputed11,12; and the time scales for the cores are also disputed, with consequent disagreements about correlations13-17

Results which lend support to the astronomical hypothesis come from flights of coral reef terraces that occur in rapidly rising areas, and which have been dated by <sup>230</sup>Th/<sup>234</sup>U. The important results are from Barbados<sup>4,18,16</sup> New Guinea<sup>20-22</sup>, and the Ryukyu Islands<sup>23,24</sup>. Age estimates for Upper Quaternary sealevel maxima agree closely between the areas22, and from New Guinea the record is especially good. The recurrence of transgression-regression cycles with a period of about 20,000 yr has been claimed to reflect the precession effect upon Pleistocene climates<sup>4,20</sup>. and the New Guinea sealevel curve correlates strongly with isolation changes over the last 0.23 Myr (ref. 25). Figure 1 shows sea level level changes during that period, together with  $\delta^{18}O$  records from deep-sea cores from the Caribbean26, and the equatorial Pacific27. Orbital perturbation effects for the same period are also shown. To allay previous disputes about time scales and palaeosealevels, these curves will be discussed more fully.

The sealevel curve is based on the series of transgressionregression cycles identified from successions of offlapping coral reefs, mainly in New Guinea, which have been dated precisely by <sup>230</sup>Th/<sup>234</sup>U with supporting <sup>14</sup>C data<sup>20-22</sup>. The estimated magnitudes of sealevel oscillations, and the basis for separating tectonic and eustatic effects have been explained20-22. The curve for the past 0.14 Myr is taken directly from the most recent results, and this is highly in agreement with the less complete Barbados record<sup>22</sup>. The curve before 0.14 Myr is an updated version of that published earlier20,21, based on precise levelling and field observations which I made in 1973, and which will be published elsewhere. The only significant difference between the new and the earlier curve is that the regression between 0.17 Myr and 0.14 Myr achieved a level of at least -100 mand possibly lower (as against the previous estimate of -55 m or lower). The  $\delta^{18}$ O curves shown are from Caribbean core P6304-8 (ref. 26) and equatorial Pacific core V28-838 (ref. 27); both are based on the pelagic foram, Globigerinoides sacculifera. The time scale for the cores was given by Shackleton and Opdyke<sup>27</sup>, and was based on clear identification of the Brunhes-Matuyama magnetic boundary, and the assumption of constant sedimentation rate. This time scale is very similar to that proposed by Broecker et al.<sup>14,17</sup>, and is about 25% longer than that proposed by Emiliani<sup>16,26</sup>. The critical issue of a time scale for the cores is subject to a significant scatter in reported U-series age determinations, and opinions diverge about core dating by this method<sup>13-15</sup>. To find additional support for the shorter time scale, Emiliani et al. argued that the generalised palaeotemperature curve shows good peak correspondence with the 65°N isolation curve3, and with dated raised beaches16. Many statistical arguments of this kind are, however, incorrectly founded25, and there is no significant correspondence between the New Guinea sealevel curve and Emiliani's generalised palaeotemperature curve<sup>25</sup>. I concur<sup>25</sup>, however, with the results of Kemp and Eger<sup>28</sup>, which support a significant correspondence between Emiliani's curves and the high latitude insolation curve. The correlation is not as strong as those evident in Fig. 1, however, and this presentation of the most accurate sealevel and  $\delta^{18}$ O results to date is taken as resolving the time scale argument for deep-sea cores in favour of the Broecker-Shackleton-Opdyke scale.

The most important features of Fig. 1 are first, the large number of peak-to-peak correspondences, especially between the sealevel curve and the precession-dominated curve of variations of Earth-Sun distance; second, the small degree of comparability between sealevel and δ18O curves in terms of relative amplitudes of oscillations; and third, the greater excursions of δ<sup>18</sup>O shown in the Caribbean core relative to the Pacific core (true also for other Atlantic and Caribbean cores<sup>29</sup>). These facts have extensive implications for ice age mechanisms. The very strong correspondence between fluctuations in sealevel and variations of the mean solar distance shows that the growth and decay of high latitude icesheets is influenced very strongly by insolation at low latitudes (that is because precession effects dominate insolation curves at low latitudes; obliquity dominates at high latitudes).

Control of Quaternary climatic fluctuations by variations in insolation at low latitudes was suggested by Broecker<sup>4,30</sup>: it is to be expected on meteorologic grounds<sup>31</sup>; and the principle is reinforced by the finding<sup>32</sup> that radiation input at high latitudes is quite inadequate to have caused Late Wisconsin deglaciation in the time available.

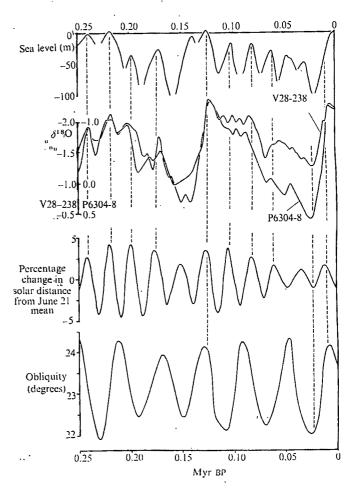

Fig. 1 Sea levels, δ<sup>18</sup>O variations, and orbital perturbation effects for the last 250,000 yr. Emiliani's results<sup>26</sup> for core P6304-8 are plotted on the time scale of Shackleton and Opdyke<sup>27</sup> (see text). P6304-8, Atlantic core<sup>26</sup>; V28-238, Pacific core<sup>27</sup>.

The Laurentide and Fennoscandian ice sheets—over 85% of the Pleistocene ice excess<sup>8</sup>—were nourished principally from the North Atlantic<sup>8,33</sup>, into which the Gulf Stream-North Atlantic current is the major conveyor of heat.

The relative amplitude differences between sealevel and  $\delta^{\iota s} \mathrm{O}$  curves are important, as the latter have often been argued to be directly indicative of the former<sup>34-36</sup>. The greatest discrepancy is between 0.115 Myr and 0.08 Myr, when two sealevel oscillations of about 50 m occurred: from the δ18O record, Shackleton27 has inferred approximately constant temperatures and sea levels, fluctuating within a 15 m range. From 0.075 Myr to 0.015 Myr the amplitudes of sealevel oscillations are again underestimated using  $\delta^{18}$ O. There is also an important shift in the mean  $\delta^{18}$ O level. For the Pacific core,  $\delta^{18}$ O is about +0.25%with respect to the mean Holocene level, from 0.115-0.08 Myr; from 0.075-0.015 Myr the shift is about +0.75%. The sealevel curve shows that considerable icecaps waxed and waned from 0.12-0.08 Myr BP, thus δ18O evidence suggests either that mean temperatures were considerably higher during this period than in the next 0.065 Myr, or that the icesheets formed around 0.11 Myr BP and 0.09 Myr BP were not as relatively poor in <sup>18</sup>O as those from 0.075 Myr BP to 0.015 Myr BP. The latter hypothesis may be simply evaluated. Mean sealevel between 0.115 Myr BP and 0.08 Myr BP (about 1% of mean ocean depth). Mean ocean enrichment of  $\delta^{18}$ O was  $\approx 0.25\%$  and therefore ice formed should show  $\delta^{18}$ O impoverishment by -25%. For the period 0.075-0.015 Myr BP was about -75 m, and with mean ocean  $\delta^{18}0 \simeq 0.75$ , ice formed in that period would show  $\delta^{18}O \simeq -37\%$ . Such a  $\delta^{18}O$  shift pattern is evident in the Greenland ice core<sup>37</sup>. These estimates indicate the general result of ocean volume change, and are not intended to negate palaeotemperature inferences (the effect of which the uptake of <sup>18</sup>O by marine organisms, has been well demonstrated<sup>38</sup>).

If the amplitudes of oscillations in the  $\delta^{18}$ O curves are low compared with the sealevel curve, that can be explained partly by mixing in the sea-bottom sediment<sup>27</sup>, and by the vertical migration of pelagic forams in response to glacial-interglacial salinity changes<sup>39</sup>. It is also partly explicable in terms of the  $\delta^{18}$ O distribution in precipitation over the icecaps. Precipitation at the centre and northern sector of the Laurentide icecap is likely to have been impoverished by about 20%, relative to the southern margin<sup>40</sup>. During icecap retreat, the water returned to the ocean was mainly from the periphery and the southern sector until the retreat was well established, whilst snow continued to fall over the icecap centre. This snow may have been more than 10% depleted in 18O, with respect to the meltwater. Although deep ice flow would move highly <sup>18</sup>O-deficient ice from the centre outwards, the rate would be slow compared with wastage of the flanks<sup>40,41</sup>. Thus the mean 818O level should rise during icecap retreat (up to a certain stage of icecap diminution), and the ocean δ<sup>18</sup>O swing is therefore reduced relative to the sealevel swing. Estimation of the magnitude of this 'fractionation' effect requires careful modelling.

There are two possible explanations for the apparent shift about 0.08 Myr ago in the mean δ18O value of icecapnourishing snow. A change of climate may have occurred, so that the moisture-bearing airmasses which originated over warmer oceans before 0.08 Myr BP, originated over cooler oceans subsequently. Alternatively, the icecaps around 0.112 Myr BP and 0.095 Myr BP may have been nearly as extensive at the later (Main Wisconsin) sheets, but only about half as thick. These alternatives are deduced from the pattern of  $\delta^{18}$ O values over high northern latitudes, reported by Dansgaard and Tauber40. The ocean temperature effect is illustrated by the  $\delta^{18}O$  difference between precipitation over water fed by the Gulf Stream at 60°N in the Norwegian Sea (-7%) and at the same latitude in the Labrador Basin (about -15%). The mean surface water temperature difference is about 6° C. The altitudinal effect is indicated by an impoverishment of up to 20% in the precipitation over central Greenland, relative to the coasts (a height difference of about 2.5 km).

The  $\delta^{18}$ O shift of about -10% around 0.08-0.07 Myr BP in the ice core from Camp Century, Greenland37, suggests that there was a simultaneous alteration of high latitude climate. This is because Greenland ice is very unlikely to have been 1 km thicker than at present during main Wisconsin times, for dynamical reasons (1 km is approximately the additional elevation needed to produce the observed  $\delta^{18}$ O shift by the altitude effect). The altitude effect cannot be ruled out for the inferred Laurentide and Fennoscandian icecaps of around 112 Myr BP and 95 Myr BP, as these were not dominated by an ocean boundary; however, a climatic change influencing Greenland would have affected these also. The ocean temperature effect on δ<sup>18</sup>O levels in snowfall seems to be implicated. The warmer sources of ice-nourishing precipitation 0.12-0.08 Myr BP were either the northern Atlantic or the Arctic Oceans. For the  $\delta^{18}$ O effect to have stemmed from the Arctic, the Arctic Ocean must have been open water, a condition likely to be stable42 even with a moderate ice cover on the encircling land masses. Open water in the Arctic, suggested by Ewing and Donn<sup>43,44</sup> as a likely factor in initiating glaciation, would lead to mean Arctic surface water temperatures up to 9°-C higher<sup>42</sup>. Arctic deep-sea cores indicate an ice cover on the sea over the last 70 Myr (refs 45 and 46), but interpretations differ for the core record before that time. The evidence from core T3-67/11 is that foram productivity was much greater from about 0.13-0.07 Myr BP than in either the preceding or succeeding 0.07 Myr (ref. 45). Such heightened productivity is consistent with open water in the Arctic45,46. Detailed analysis of further cores is necessary. It may be that the record from the Norwegian Sea, which Kellog<sup>47</sup> amply demonstrated to have been considerably more ice-bound than at present during the last 0.12 Myr indicates sufficiently that the Arctic is unlikely to have been ice free. The conditions of the ocean surface in the northern Atlantic must therefore have altered substantially between 0.08 Myr and 0.07 Myr ago, with probably a fall of temperature and perhaps a major expansion of ice cover over the sea.

Rather rapid alterations of regional climate, occurring well after glaciation is established, may thus be responsible for important differences between  $\delta^{18}O$  and sealevel records for the last 250,000 yr. Within glacial epochs, icecaps oscillated in size with about a 20,000-yr period. When orbital eccentricity is large, icecap growth and decay is synchronous with precession-induced variations of mean solar distance at the summer solstice. These facts must be incorporated in any adequate theory of ice ages.

### Statistical geometrical approach to random packing density of equal spheres

### Keishi Gotoh

Department of Chemical Process Engineering, Hokkaido University, Sapporo, Japan

### John L. Finney

Department of Crystallography, Birkbeck College, London WC1E 7HX, UK

A statistical geometrical argument is presented which could, as the basis of a more refined calculation, help to give a statistical geometrical answer to the question of what random packing is.

'WHAT is random packing?' That question has been much discussed since random packings of spheres were first proposed as models of simple liquid structure1-6. Experimental determinations of the maximum packing density agree on a value of about  $0.636 \pm 0.001$  (refs 7-16), but there is still no satisfactory statistical geometrical theory to explain this value, though a rough explanation based on coordination number distribution has been given by one of us17. Moreover, the lower limit of stability of a random packing occurs at a density of about 0.60 (refs 9-13); no explanation of this 'random loose packing' figure exists. We present here a statistical geometrical argument which derives a packing density of 0.6357 in excellent agreement with the recognised experimental values. We also obtain a lower stability bound at a density of 0.6099, which we suggest corresponds to the random loose-packing.

### The statistical argument

Our argument is threefold:

(1) As a consequence of a stability criterion, the average coordination number in the packing should be 6.0.

(2) As first pointed out by Bernal<sup>5</sup>, the random packing can be thought of as a collection of tetrahedral aggregates of spheres. We calculate the most probable shape of the characteristic tetrahedron.

(3) We then deduce the overall packing density from that of the most probable tetrahedron.

### Average coordination number

For a given sphere to be stable against displacement in a given direction, it must be supported by three spheres in that direction, the group of four spheres forming a tetrahedron. The same stability criterion must also apply for the opposite direction, implying thus a coordination number average of 6. This proposition was examined by Heppes<sup>18</sup> for a serially-deposited packing in which no rearrangements are permitted. Bennett19 later argued that the same should be true of a packing further densified by shaking or otherwise. Figure 1 is a plot of the average coordination number against radial distance for the full Finney 7934 centre close-packed model<sup>20</sup> and shows an average of 6 (allowing for experimental errors in the sphere coordinates). Each point is the average value of 500 to 700 central spheres and full curve is the data line of Mason<sup>21</sup>. A recent study22 on a simulated very slow settling of rigid equal spheres into a randomly packed bed gives also an average coordination number of 6.0, with an overall packing density of

#### The most probable tetrahedron

Consider a tetrahedron formed by an arbitrary sphere and three supporting spheres. We postulate that the three supporting spheres supporting a central sphere are oriented according to a probability that is proportional to that projected surface area of the spherical envelope at R = 1.0 diameters which can be seen from a long distance from the supported sphere. We ignore the possible restricting effect of the neighbours on the configuration of the three supporting spheres.

In the coordinate system shown in Fig. 2a, we calculate the expected z coordinate of a first supporting sphere. The elementary annular surface area of the spherical envelope at  $z = z_1$ which can be seen from distant z direction is

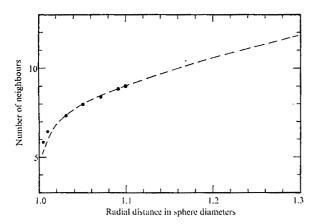

Fig. 1 The average number of neighbouring spheres within the radial distance R in units of the sphere diameter.  $\bullet$ , this experiment; --, ref. 21.

$$dS = 2\pi r_1 \cdot d\varphi_1 \sin \varphi_1 = 2\pi z_1 dz_1$$

where the subscript 1 denotes the first supporting sphere. The probability that the z coordinate of the first supporting sphere lies between  $z_1$  and  $z_1 + dz_1$  becomes

$$f(z_1) dz_1 = (2\pi z_1 dz_1)/(\int_0^1 2\pi z_1 dz_1) = 2z_1 dz_1$$
 (1)

where  $f(z_1)$  is the probability density function, and the denominator in the middle term of equation (1) expresses the total area available for the first sphere. From equation (1) the expected value of  $z_1$  becomes

$$\bar{z}_1 = \int_0^1 z_1 \cdot f(z_1) \, dz_1 = 2/3$$
 (2)

where our units are sphere diameters.  $\bar{z}_1$  is the largest of the z coordinates of the three supporting spheres.

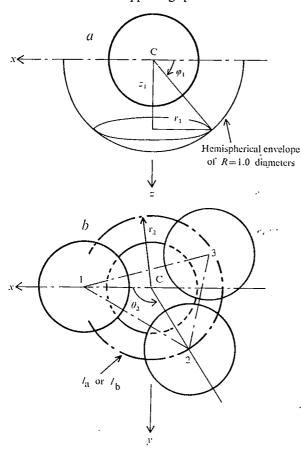

Fig. 2 The coordinate system. C denotes the central sphere; 1, 2, 3, the supporting spheres;  $I_a$  or  $I_b$ , the length used in equation (3).

We can partially test our assumptions and argument so far with reference to the 7934 centre packing. We first define the 'shortest zig-zag path' between the arbitrary spheres S and E (Fig. 3). Around the sphere S and on the side of the sphere E we search sphere centres lying within the hemispherical volume of radius R. We simultaneously obtain the distance  $D_i$  from each sphere centre to the line SE and also the SE-directional

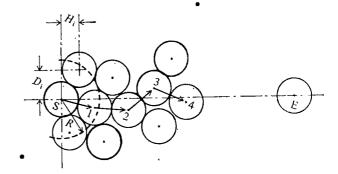

Fig. 3 The shortest zig-zag path.

component  $H_i$  of the distance from the sphere S to each sphere centre. Then we move from the sphere S to the next central sphere 1 which lies nearest to the line SE (that sphere for which  $D_i$  is minimum). The procedure is repeated until we reach the sphere E. In this way we have obtained information on the packing structure along with the length of the shortest zig-zag path between two arbitrary spheres. The first supporting sphere as defined above lies on the shortest zig-zag path, and equation (1) expresses the  $H_i$  distribution of the shortest zig-zag path, which agrees on average with the experimental result fairly well (Fig. 4).

For ease of later calculation, we now fix the first supporting sphere at the point  $(\sqrt{5/3}, 0, 2/3)$ —we place the sphere on the xz-plane. Our final result is independent of this choice provided  $\bar{z}_1 = 2/3$ .

Subject to the existence of the first supporting sphere, we now calculate the expected z coordinate of a second supporting sphere. The projected surface area of the spherical envelope which can be seen from distant z direction becomes (Fig. 2b)

$$S_{2} = \int_{z_{2}=0}^{z_{2}=2/3} l_{a} \sin \varphi_{2} d\varphi_{2} + \int_{z_{2}=2/3}^{z_{2}=z_{*}} l_{b} \sin \varphi_{2} d\varphi_{2}$$

$$= \int_{0}^{2/3} [(l_{a} z_{2} dz_{2})/\sqrt{(1-z_{2}^{2})}] + \int_{2/3}^{z_{*}} [(l_{b} z_{2} dz_{2})/\sqrt{(1-z_{2}^{2})}]$$

$$= \int_{\sqrt{5/3}}^{1} l_{a} dr_{2} + \int_{r^{*}}^{\sqrt{5/3}} l_{b} dr_{2}$$
(3)

where

$$l_{a} = 2 \int_{-r_{2}}^{A} [(r_{2} dx_{2})/\sqrt{(r_{2}^{2} - x_{2}^{2})}]$$

$$= 2r_{2} \left[ \sin^{-1} \frac{(5/9) - (1 - r_{2}^{2})}{2r_{2}\sqrt{5/3}} + \frac{\pi}{2} \right]$$
with  $A = (5/9 - z_{2}^{2})/(2\sqrt{5/3})$ 
and  $l_{b} = 2 \int_{-r_{2}}^{B} (r_{2} dx_{2}/\sqrt{(r_{2}^{2} - x_{2}^{2})})$ 

$$= 2r_{2} \left[ \sin^{-1} \frac{(1 - 4\sqrt{(1 - r_{2}^{2})/3})}{2r_{2}\sqrt{5/3}} + \frac{\pi}{2} \right]$$

with 
$$B = (1-4z_2/3)/(2\sqrt{5}/3)$$
  
and  $r_* = \sqrt{(1-z_*^2)} z_* = (2+\sqrt{15})/6$ 

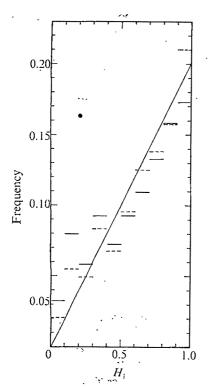

Fig. 4 The  $H_i$  distribution for the spheres on the shortest zig-zag paths. Full line, Equation (1); —— and – – –, experiments for R = 1.005 and R = 1.01, respectively.

The  $I_a$  term is obtained for the restrictions  $(x_2-\sqrt{5/3})^2+y_2^2 \ge 1$  and  $z_2 \le 2/3$ ; the  $I_b$  term for  $(x_2-\sqrt{5/3})^2+y_2^2+(z_2-2/3)^2 \ge 1$  and  $z_2 \ge 2/3$ . Using equation (3), the expected z value of the second supporting sphere becomes

$$\overline{z}_2 = (\int_{\sqrt{5/3}}^1 z_2 \, l_a dr_2 + \int_{r_*}^{\sqrt{5/3}} z_2 \, l_b dr_2) / S_2 = 0.61154365$$
 diameters (4)

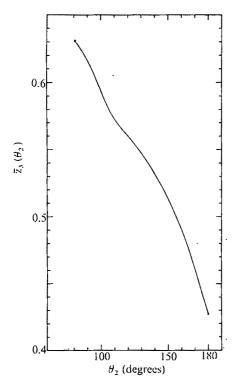

Fig. 5  $\bar{z}_{3}(\theta_{2})/\theta_{2}$  relation.

where  $z_2 = \sqrt{(1-r_2^2)}$ . Although  $\bar{z}_2$  has been obtained, expected values of  $x_2$  and  $y_2$  remain unknown. We now express the coordinates of the second supporting sphere as  $(r_2 \cos \theta_2, r_2 \sin \theta_2, 0.61154365)$ , where  $r_2 = \sqrt{(1-\bar{z}_2^2)}$  (see Fig. 2b).

For a given value of  $\theta_2$  we can now calculate the projected surface area  $S_3$  of the spherical envelope on which the centre of a third supporting sphere lies, subject to the following conditions: (1) the centre of the third supporting sphere lies on the surface of the spherical envelope and we require the projected area which can be seen from distant z direction; (2) the three supporting spheres do not intersect amongst themselves $d_{13} > 1$  and  $d_{23} > 1$  (where  $d_{ij}$  denotes the distance between the two sphere centres, i and j.); and (3) the triangle consisting of the centres of the three supporting spheres, which can be seen from distant z direction, must include the projected centre of the central sphere (Fig. 2b). This is the stability condition for the central sphere. As is seen from Fig. 2b, we need consider only one side of xz plane, and sphere 2 touches sphere 1 st  $\theta_2 = 80.995^{\circ}$ , giving the range of  $80.995^{\circ} \le \theta_2 \le 180^{\circ}$ . On the way to calculating numerically the projected surface area  $S_3$ , we can simultaneously obtain the expected value  $\overline{z}_{3}(\theta_{2})$  of the third supporting sphere for  $\theta = \theta_2$ . In the numerical calculation, minute surface areas satisfying the above three conditions were summed up for a fixed z value. In this way we obtain the  $\theta_2 / \overline{z}_3(\theta_2)$  relation and its mathematical mean value becomes

$$\bar{z}_3 = \int_{80.995^\circ}^{180^\circ} \bar{z}_3 (\theta_2) d\theta_2 / (180^\circ - 80.995^\circ) = 0.54093$$
 (5)

 $\bar{z}_3$  ( $\theta_2$ ) decreases monotonically with increasing  $\theta_2$  (Fig. 5); we find  $\bar{z}_3=0.54093$  corresponds to  $\theta_2=134.53^\circ$ . Thus we have determined the expected coordinates of the second supporting sphere. We now express the expected coordinates of the

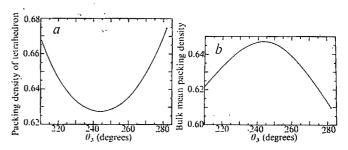

Fig. 6 a, Probable packing density of the tetrahedron. b, Probable density of the random packing.

third supporting sphere as  $(r_3 \cos \theta_3, r_3 \sin \theta_3, 0.54093)$ , where  $r_3 = \sqrt{1-\overline{z}_3^2}$ , and sphere 3 touches sphere 2 and sphere 1 at  $\theta_3 = 210.44^\circ$  and 281.93°, respectively, giving a possible range of  $210.44^\circ \le \theta_3 \le 281.93^\circ$ .

Next we consider the tetrahedron consisting of the centres of the central sphere and the three supporting spheres. The packing density  $\Psi$  of the spheres in the tetrahedron can be expressed by a function of  $\theta_3$ , the  $\Psi/\theta_3$  curve being U-shaped with upper bounds of about 0.667 and 0.675 with a minimum of 0.627 (Fig. 6a). The position of the third supporting sphere, in other words  $\theta_3$ , is still unknown at this stage.

The formulae used in the above calculation are collected in ref. 23.

#### Overall packing density

So far we have discussed only the most probable shape of the tetrahedron, a collection of which constitutes the random packing. As the tetrahedron cannot be considered to be a 'unit cell' of the packing, its density will not necessarily correspond to the bulk density. Instead, we refer to Finney's polyhedral analysis<sup>16</sup> in which the packing of spheres is considered in terms of the packing of the 'Voronoi polyhedron' or

'Dirichlet region' (refs 24, 25), and relate part of the most probable tetrahedron discussed above to the most probable Voronoi polyhedron. We postulate that this average polyhedron is characteristic of the packing, and thus gives us the bulk packing density.

First we bisect perpendicularly the distances between the central sphere and the three supporting spheres by three planes, dividing the tetrahedron into two parts. The inner part, the central sphere side, is considered as a representative angular segment of the Voronoi polyhedron confining the central sphere, since the most probable tetrahedron is discussed for an arbitrary direction and the system must be isotropic overall. Thus we can calculate the packing density of the angular segment, that is the bulk mean density  $\psi_{\text{bulk}}$  of the random packing. As is shown in Fig. 6b, the  $\Psi_{bulk}/\theta_3$  curve is convex with lower bounds of 0.6099 and 0.6220, with a maximum of 0.6472, and a mathematical mean value of 0.6357. Since no criterion is available for determining  $\theta_3$ , we suggest the mathematical mean value is the expected bulk mean density of the random packing; namely, that the random packing density of equal spheres is 0.6357 (with possible bounds of 0.6099 and 0.6472), in excellent agreement with the recognised experimental maximum value of 0.636  $\pm$  0.001 (refs 7-16). In addition, the stability criterion implies upper and lower density bounds of 0.6472 and 0.6099. The latter we suggest might be identified with the random loose packing.

### Validity and application of the technique

Our argument is not rigorous, but its consistency with experiment is encouraging. In particular, we stress the following problems: (a) the average coordination of 6 is still open to argument, although the experimental data support it, even for the close-packed aggregate; (b) we have ignored the restrictive effects of neighbouring configurations, and so probably underestimated cooperative geometrical effects; (c) we have prematurely averaged our distributions. More elaborate calculations could avoid this objection, and would presumably give a  $\theta_3$ :  $\Psi$  distribution having a slightly different shape and bounds.

Thus we must be wary of assigning too much significance to the actual values obtained. The mean value 0.6357 is temptingly close to the accepted experimental maximum density values of Scott12 and of Finney16 (0.6366  $\pm$  0.0008 and 0.6366  $\pm$  0.0004 respectively) but we cannot assert definitely that the mean value should necessarily correspond to that maximum density obtained in the laboratory. We might rather suggest that the laboratory maximum density should correspond to our upper bound of 0.6472, while the lower bound of 0.6099 should refer to the minimum packing density for an isotropic stable packing—the so-called random loose-packing. If this assignment is correct, both bounds are about 0.01 too high, a discrepancy which may be due to our admittedly premature averaging; alternatively, both the Scott and Finney packings may not have been true maxima.

This work was started at Birkbeck College. K.G. thanks the Japanese Ministry of Education for a visiting Research Fellow-

### Structural uniqueness of lactose operator

### Hardy W. Chan & Robert D. Wells

Department of Biochemistry, College of Agricultural and Life Sciences, University of Wisconsin, Madison, Wisconsin 53706

The repressor binding capacity of hplac DNA was maximally reduced by as few as 2-5 cuts by either of two single-strand specific nucleases. But approximately 300 cuts by three nonspecific nicking agents were necessary to give the same effect.

THE properties and conformation of DNA are dictated by nucleotide sequence<sup>1,2</sup>. This conclusion was derived from at least fourteen different chemical, physical, enzymatic and biological studies on twelve high molecular weight duplex DNAs with defined repeating nucleotide sequences. The effect of sequence on structure was apparent with these DNA polymers since the influence was magnified compared with natural DNAs whose properties are a composite of many types of sequence effects.

We are extending these studies by attempting to determine if

natural DNA has the same conformation throughout its entire length or if different structures exist at various sites along the chain. It is presumed that regions with 'anomalous' conformations are present in small amounts compared with the bulk DNA (which may be in a typical DNA B configuration). Thus, a highly sensitive and specific assay is needed to detect regions with unique conformations. Also, if these odd regions are present in small amounts, they may serve as regulatory sites, instead of structural genes. Their uniqueness may contribute to the high degree of specificity and tightness of binding of regulatory proteins.

The lac repressor plus λplac DNA system<sup>3</sup> provides a highly sensitive and selective assay for a specific region of DNA, since the repressor binds to operator DNA with a remarkably large equilibrium constant4 and does not perform complex catalytic or translocating functions. Nucleases with defined specificities were used as selective probes for assessing the

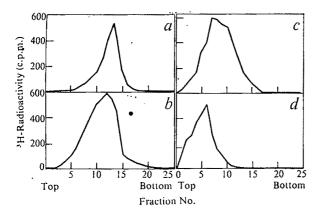

Fig. 1 Alkaline sucrose gradient profiles of <sup>3</sup>H-λplac DNA rig. 1 Aikaine sucrose gradient profiles of 'H-Apiac DNA treated with  $S_1$  nuclease. For preparation of  $\lambda$ plac 5 phage, medium J (ref. 14) was used but with 10 µg ml<sup>-1</sup> of thymidine and 0.4% of glucose instead of lactose. <sup>32</sup>P and <sup>3</sup>H-thymidine-labelled  $\lambda$ plac 5 DNA was prepared from strain JG 108  $\lambda$ plac (provided by A. Riggs). A 100 ml culture was grown at 30° C to an A of 0.4 and induced at 45° C for 15 min. 2 mCi of <sup>32</sup>P-phosphate or <sup>3</sup>H-thymidine was added on induction and the culture was shifted to  $37^{\circ}$  C and incubated for an additional the culture was shifted to 37° C and incubated for an additional 3 h. Cells were centrifuged, resuspended in 10 ml of Φ80 buffer (50 mM NaCl, 1 mM MgSO<sub>4</sub>, 20 mM Tris-HCl, pH 7.4) and lysed with chloroform. After centrifugation, the phage were concentrated with polyethylene glycol 6,000. The precipitated phage were centrifuged and resuspended in 5 ml of Φ80 buffer. Solid CsCl (optical grade) was added to a final density of 1.49 g ml<sup>-1</sup> and this suspension was centrifuged for 14 h at 35,000 r.p.m. in a Spinco Ti-50 rotor. Phage, purified from two cycles of CsCl gradients, were dialysed against DB I (10 mM Tris-HCl, pH 7.4, 10 mM MgSO<sub>4</sub>). The DNA was extracted from the phage by rolling the solution with an equal volume of phenol six times and the excess phenol was removed by six ether extractions. The aqueous layer was dialysed exhaustively against and subsequently stored in DB II (2 M NaCl, 10 mM Tris-HCl, pH 7.4, 0.1 mM EDTA). Immediately before use, DNA stored in DB II was dialysed against DB III (10 mM Tris-HCl, pH 7.4, 0.1 mM EDTA). All dialysis tubing was autoclaved and stored in sterile buffer before use. DNA prepared by this procedure contained few, if any, detectable single-strand scissions (a). S<sub>1</sub> nuclease was purified to 23 units mg<sup>-1</sup> by the procedure of Vogt<sup>6</sup>. Reactions with S<sub>1</sub> nuclease contained 10 mM ammonium acetate (pH 5.0), 1 mM ZnSO<sub>4</sub>, 50 mM NaCl, 15 µg ml<sup>-1</sup> of <sup>3</sup>H-λplac DNA and variable amounts of S<sub>1</sub> nuclease. We define one unit of S<sub>1</sub> nuclease as the amount of enzyme required to render acid soluble 25 nmol of <sup>3</sup>H-(dA-dT)<sub>n</sub> (dA-dT)<sub>n</sub> per min at 37° C in a 100 μl reaction mixture containing 650 nmol of 3H-(dA-dT)n (dA-dT)n instead of \(\lambda plac DNA\). Reactions (0.10 ml) were performed at C for 30 min and were terminated by addition of EDTA (to 25 mM). The reaction products were extracted three times with phenol and six times with ether. Recovery was greater than These samples were subsequently used for molecular weight determinations or repressor binding studies. Linear 5 to 20% (w/v) alkaline sucrose gradients were made in 0.3 M NaOH, 0.7 M NaCl, and 1 mM EDTA. DNA samples (50  $\mu$ l) were layered on to the gradients and were centrifuged at 45,000 r.p.m. for 2.5 h at 4° C in an SW 50.1 rotor and the radioactivity of 0.2 ml fractions was determined. Molecular 0.2 ml fractions was determined. Molecular weights of the DNA fragments were calculated relative to markers of intact λDNA and ΦX174 DNA (from J. Dodgson). a, No S<sub>1</sub> nuclease; b, 0.1 units nuclease; c, 1 unit nuclease; d, 10 units nuclease. Fraction 13,  $15 \times 10^6$ ; fraction 10,  $7 \times 10^6$ ; fraction 7,  $3 \times 10^6$  and fraction 5,  $1 \times 10^6$ .

structural uniqueness of the operator DNA. The comparative ability of two single-strand specific nucleases (mung bean and  $S_1$  nuclease) and of three nonspecific nicking agents (pancreatic DNase, micrococcal nuclease and sonication) to abolish repressor binding ability as a function of reduction in DNA molecular weight was determined.

#### Single-strand specific nucleases

 $S_1$  nuclease cleaves double-stranded  $\lambda plac$  DNA into large fragments even though it has an absolute preference for single-stranded over double-stranded DNA<sup>5,6</sup>.  $^3H$ - $\lambda plac$  DNA was degraded by  $S_1$  nuclease to different extents and the sizes of

the DNA fragments were determined on 5-20% alkaline sucrose gradients (Fig. 1). Under the conditions used, treatment with 1 and 10 units of nuclease caused an average molecular weight reduction from  $30\times10^6$  (undegraded) to  $6\times10^6$  and  $4\times10^6$ , respectively. If the DNA were single stranded, the latter concentration of enzyme was sufficient quantitatively to degrade the DNA to acid-soluble fragments (results not shown).

Gel electrophoretic analyses were performed on 0.6% agarose gels on selected DNA fragments, which had been denatured, to provide a separate determination of molecular weights and to provide greater resolution. Figure 2 shows the distribution of S<sub>1</sub> nuclease-generated fragments and the distribution of molecular weight markers. Substantial agreement was found between the positions of the shoulders on the sucrose gradient analysis (Fig. 1) at fractions 5, 7 and 10 and the sizes of the predominant species on gel analysis (Fig. 2) at fractions 45, 37 and 30, representing molecular weights  $1.2 \times 10^6$ ,  $3 \times 10^6$  and  $7 \times 10^6$  respectively. Also, both analyses showed the virtual absence of undegraded DNA (15×106, single-strand molecular weight) and of small fragments (<100,000) consistent with the expected mode of action of S<sub>1</sub> nuclease<sup>5,6</sup>. These analyses reinforce the validity of the size determinations. Also, the gel analyses suggest that the DNA was cut at specific sites since a nonrandom distribution of S<sub>1</sub> fragments was generated (compare with distribution of Eco R<sub>1</sub> fragments in Fig. 2).

The ability of the  $S_1$  nuclease fragmented  $^3H$ -DNA to compete against undegraded  $^{32}P$ -DNA for *-lac* repressor is shown in Fig. 3. The more highly degraded DNAs bind repressor less well.

Figure 4 correlates the data from the first three figures and shows that a small reduction in molecular weight caused by  $S_1$  nuclease provides a large reduction in repressor binding activity. The binding was reduced 50% when the  $\lambda plac$  DNA (molecular weight,  $30\times10^{\circ}$ ) was degraded into fifths (molecular weight,  $6\times10^{\circ}$ ). If this number of scissions occurred on a random basis, the repressor binding ability of the DNA should be unaltered (<1% reduction).

Studies were performed also with the mung bean nuclease which prefers single-stranded over double-stranded DNA by a

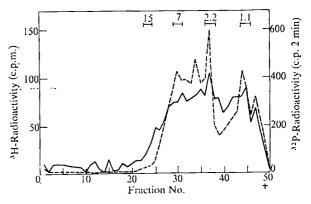

Fig. 2 Agarose gel electrophoresis of  ${}^3\text{H}-\lambda\text{plac}$  DNA treated with  $S_1$  nuclease. (—),  ${}^3\text{H}-\lambda\text{plac}$  DNA treated with 1 unit of  $S_1$  nuclease, as described in Fig. 1c; (---), fragments of  ${}^3\text{P}-\lambda\text{plac}$  DNA treated with the Escherichia coil  $R_1$  restriction enzyme (from B. Weisblum). The Eco $R_1$  reaction mixture contained 100 mM Tris-HCl (pH 7.4), 5 mM MgCl<sub>2</sub>, 5.75 µg ml-1  ${}^3\text{P}-\lambda\text{plac}$  DNA and sufficient enzyme to degrade all  ${}^3\text{P}$ -DNA .The 50 µl reactions were incubated at 37° C for 15–30 min.  ${}^3\text{H}$ -sample DNA and Eco $R_1$  restricted  ${}^3\text{P}-\lambda\text{plac}$  DNA markers were denatured with 0.2 volume of 2 M NaOH and were made 10% in sucrose and 0.04% in bromophenol blue. The mixture was electrophoresed for 5 h at 5 mA per gel at room temperature on 0.6% w/v agarose gels16, with continuous circulation of the electrophoresis buffer (36 mM Tris, 30 mM NaH<sub>2</sub>PO<sub>4</sub>, 1 mM EDTA, 0.05% SDS (pH 7.7)) between the upper and lower chambers. Transverse 3 mm gel slices were dissolved in 1 ml water by autoclaving and radioactivity was determined. The 15 × 106 molecular weight marker was unfragmented, but denatured,  $\lambda\text{plac}$  DNA. Solid line,  ${}^3\text{H}$ ; broken line,  ${}^3\text{P}$ .

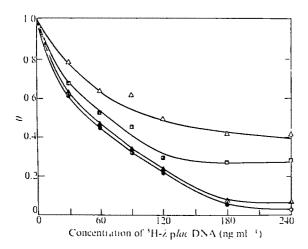

Fig. 3 Repressor binding ability of λplac DNA treated with S<sub>1</sub> nuclease. <sup>3</sup>H-Aplac DNA was treated with variable amounts of S<sub>1</sub> nuclease (see Fig. 1) and the affinity of the nuclease-nicked <sup>3</sup>H-λplac DNA for the lactose I<sup>sQ</sup> repressor (provided by A. Riggs) was determined by competition equilibrium experiments as described. The operator active repressor was determined as described and was at least 95% pure. Various amounts of test  $^3\text{H-}\lambda\text{p}/ac$  DNA were mixed with 0.03 µg of intact  $^3\text{P-}\lambda\text{p}/ac$  DNA in 0.5 ml of BB1. After addition of repressor (1.2  $\times$  10<sup>-15</sup> mol), the mixture was incubated for at least 30 min at room temperature; 0.2 ml aliquots were then filtered in duplicate through nitrocellulose membranes (pretreated as described14 The membrane filters were washed once with 0.4 ml of FB1 dried, and radioactivity was determined. Each experimental point is the average of two filters; reproducibility was  $\pm 10\%$ .  $\blacktriangle$ , No enzyme;  $\bullet$ , 0.1 units;  $\blacksquare$ , 1 unit;  $\uparrow$ , 10 units of  $S_1$  nuclease. The repressor binding ability  $\theta$ , is the ability of the nuclease-treated <sup>3</sup>H-DNAs to compete against intact <sup>35</sup>P-λplac DNA for the lactose repressor.  $\theta$  is obtained by dividing the 32P-counts retained in the presence of competing 3H-DNA by that retained in the absence of competing DNA.

ratio of 30,000 to 1 (ref. 7). The mung bean nuclease is at least as effective as the  $S_1$  nuclease (Fig. 4) in destroying repressor binding. When approximately two double-stranded cuts were made, which decreased the molecular weight by one-third  $(10\times10^6)$ , a 50% reduction of repressor binding was found. Further degradation of the DNA with more enzyme to a molecular weight of  $0.5\times10^6$  gave only a slightly greater (60-70%) reduction in binding. The reason for the lack of total reduction in repressor binding by these two nucleases is unknown. That the mung bean enzyme is slightly more specific than the  $S_1$  nuclease may be due to its higher extent of purification and hence single-strand specificity; trace contamination with a double-strand specific endonuclease could diminish substantially the specificity demonstrated in Fig. 4.

### Nonspecific nicking agents

Since the S<sub>1</sub> and mung bean nucleases had a preferential effect on repressor binding sites, λplac DNA fragmentations were performed with pancreatic DNase, micrococcal nuclease and sonication, agents which do not have pronounced specificities. λplac DNA was degraded with pancreatic DNase over a 10<sup>16</sup> fold concentration range. The size of the products was analysed by alkaline sucrose gradient sedimentation and ranged from approximately 15 × 10<sup>6</sup> to 100,000 (duplex molecular weights) (Fig. 4). Repressor binding activity of these fragments was substantial (greater than 85%) even when the DNA was fragmented to 3% (1 10<sup>6</sup>) of its original size. To observe a 50% reduction of repressor binding ability, λplac DNA had to be degraded into fragments no larger than 100,000 in molecular weight (Fig. 4).

As it was important to determine accurately the size of the sample most highly degraded by pancreatic DNase and since this sample remained near the meniscus on an alkaline sucrose gradient, indicating a molecular weight no larger than 100,000, a determination was performed on 10% polyacrylamide gels

under established conditions. The DNA was at eps (c. 24s) pairs long indicating a molecular weight of at c. s. (d) Hence, the dual analyses set the molecular weight of (c. s. 22s) at 100,000.

Similar studies were carried out with two steal is agents for degrading DNA which gave vittal ۲¢. results. Degradations were performed with nuclease, which generates 3'-phosphoryl terrais ultrasonication, a random mechanical process c micrococcal nuclease (Worthington) contained 50 HCl (pH 7.4), 2 mM CaCl<sub>2</sub>, 15 μg ml<sup>-1</sup> of <sup>3</sup>H ?. 'ε variable amounts of micrococcal nuclease. i., ... degraded into double-stranded fragments of .r.  $15 \times 10^6$ ,  $3 \times 10^6$  and  $0.5 \times 10^6$  by both techniques . 1 shown). Repressor binding studies demonstrated  $15 \times 10^6$  and the  $3 \times 10^6$  molecular weight previous no detectable reduction in repressor binding ac vitra the  $0.5 \times 10^6$  preparations retained at least  $80^{\circ}$ , if the The results of these sonication studies are cors or previous work8 which demonstrated that  $\lambda plac$ sonicated into fragments of one million molecu a. ar. still retain full repressor binding.

Hence, the results from these three non-specific real sections are internally consistent and emphasized of nicking by  $S_1$  and mung bean nucleuse of the section of and 150 times as many cuts by the honspecific real sections binding as for the two single-strand specific enzimes

### Protection of operator by repressor

Since only a few nucleolytic scissions by the SD C and specific nucleases sufficed to diminish represent the specific nucleases are specific nucleases.

Table 1 Repressor binding ability of  $\lambda plac$  DNA treated with  $S_1$  nuclease in absence or presence of repressor

•		Molecular weight of	Repressor
Reaction	Additions ·	DNA after treatment	binding %
1	None	$30 \times 10^{6}$	100
2	S <sub>1</sub> nuclease	$4 \times 10^6$	43
3	S <sub>1</sub> nuclease +		
	repressor	$4 \times 10^6$	> 95
4	S <sub>1</sub> nuclease + denatured repressor		
	denatured repressor	$4 \times 10^6$	43

Reaction conditions were identical to those described in Fig. 1 except that no NaCl was present and 10 units of  $S_1$  nuclease was used in all cases. 0.010 ml of repressor buffer (0.13 M potassium phosphate (pH 7.2) and 5% glucose) was added as the blank to reaction 2. Lactose repressor (threefold binding saturation excess at pH 7.0) was added to the DNA and incubated at 0° C for 15 min before the nuclease was added. Denatured repressor was obtained by heating the active repressor at 100° C for 10 min. Molecular weights and repressor binding capacities were measured as described in Figs 1 and 3.

studies were performed in the presence and absence of repressor (Table 1). With a constant amount of S<sub>1</sub> nuclease, the DNA was degraded to a similar extent (molecular weight,  $4 \times 10^6$ ) in the absence or presence of repressor. This result was not surprising since the repressor should protect only a small portion of DNA (about 27 base pairs9). But when the ability of the fragmented DNAs to bind repressor was compared, substantial differences were found between fragments that were generated in the presence or absence of active repressor. A 60% reduction in repressor binding was observed when the DNA was degraded in the absence of added repressor. In contrast, when the nuclease degradation was performed in the presence of active repressor, more than 95% of repressor binding ability was retained. Also, heat-denatured repressor did not protect since the same amount of reduction in repressor binding was found when S<sub>1</sub> nuclease degradation was performed in the presence of heat-denatured repressor as in its absence. Similar experiments with the mung bean nuclease gave a result in complete agreement with the data of Table 1.

The significance of this protection is twofold. Reduction

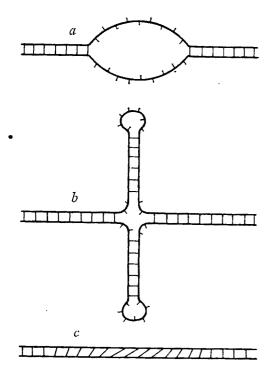

Fig. 5 Possible unique structures. a, Thermolability; b, cruciform; c, helical, non-DNA B.

of repressor binding by single-stranded nuclease treatment must be due to nucleolytic scission at sites identical or closely adjacent to the repressor binding site. Second, the recognition of the operator by the single-strand specific nucleases is not due to some artefactual conformation induced by the nuclease reaction conditions since the repressor binds specifically under the nuclease reaction conditions.

#### Effect of salt

The 'structural uniqueness' of the *lac* operator could be due to (a) a high degree of thermolability (facile breathing), (b) a unique but nonlinear structure containing some unpaired nucleotides such as a Gierer loop¹0 (cruciform) or (c) another unique conformation which is linear and fully base paired but has a different helical pitch or tilt of base pairs, such as found for certain DNA polymers¹¹². High salt concentrations should diminish the local breathing of thermolabile regions of DNA (theory a) and should diminish the tendency to form cruciforms (theory b) (in the absence of cruciform stabilising factors such as modified bases or proteins), but should have little or no effect on the tendency to adopt other unique but linear structures.

Comparative studies were performed with the  $S_1$  nuclease in 50 and in 250 mM NaCl (results not shown). Since the  $S_1$  nuclease was half as active in 250 mM as in 50 mM NaCl on a single-stranded substrate, three times as much nuclease was added to the high salt reactions to assure that the salt effect was solely on DNA conformation rather than the enzyme activity. Under both conditions, the  $\lambda plac$  DNA was fragmented to similar extents and the repressor binding ability of the treated DNA was similarly abolished; 70% reduction of repressor binding was found when the DNA was degraded in 250 mM NaCl to  $1.4 \times 10^6$  (compare with Fig. 4).

### **Models for DNA Structure**

The original goal of this study was to determine if different DNA conformations exist along a chromosome chain. Our results demonstrate that certain regions of  $\lambda plac$  DNA are quite sensitive to single-strand specific nucleases and, therefore, have structures that are different from the greater part of the DNA. This conclusion agrees with and was predicted from the results on DNA polymers<sup>1,2</sup> which revealed the influence of nucleotide sequence on DNA properties and structure.

The nature of the structural uniqueness which is recognised by the  $S_1$  and mung bean nucleases is unknown at present. Three possible models (Fig. 5) are envisaged: model a, the unique region possesses low thermostability and, hence, is in a nonhelical state for a larger proportion of the time than other regions of DNA. The low thermostability could be due to low G-C content or to the presence of modified nucleotides. Model b, the unique region could exist, at least transiently, in a cruciform structure<sup>10</sup> or other configuration which contains some nonpaired bases. Model c, the unique region may be totally helical but in a different geometric configuration (not DNA B) than the great part of the DNA chromosome. For example, the tilt of the base pairs or the helical dimensions could be somewhat altered; such helical variances have been recognised1,2 with the DNA polymers. Whatever this odd configuration may be, it must be susceptible to the single-strand specific nucleases.

The nucleotide sequence of transcripts of the *lac* promoter and operator region has been determined (ref. 9 and Dickson, Abelson, Barnes, and Reznikoff, personal communication). Though revealing several interesting sequence anomalies, these studies do not provide direct information on the conformation of these regulatory sites. Two facets of the sequence may however be relevant to this work; the potential for the formation of a cruciform exists at the presumed repressor binding site. In a run of 11 possible base pairs, 10 are true Watson-Crick pairs. Additionally, several regions of high A-T content exist

in the promoter-operator sequence. The longest contains 10 A-T pairs in a run of 12 base pairs. The significance of these regions remains to be determined.

It is not possible to distinguish between these three models on the basis of present information. The nucleolytic sensitivity of the repressor binding activity of \( \lambda plac \) DNA was insensitive to salt concentration (see above) which strongly favours model c and disfavours a and b since the parent linear duplex structures should be stabilised by salt. Also, there is little effect of temperature on the binding of repressor to λplac DNA4 which favours model c but disfavours a and b. Again, the large forward rate constant of the repressor-operator interaction4 makes probable the interaction of the repressor with a stable. not transient, unique operator configuration; this consideration favours model c and disfavours a and b. Model a is favoured by the presence of A-T-rich regions in the sequence and this model easily explains the results described here. The lac repressoroperator interactionis, however, quite sensitive to ionic strength4 which favours this model, but the sensitivity may be explicable on the basis of protein-protein, rather than protein-nucleic acid, interactions. Also, previous studies11 with DNAs of defined sequence demonstrated the need for both high A-T content and certain sequence features for effective repressor binding; low thermostability alone was not sufficient.

The cruciform model (b) is plausible because of its simplicity and because of the sequence studies but is argued against by (1) its thermodynamic improbability and (2) recent studies<sup>12</sup> which demonstrate that λplac DNA containing a high density of negative supercoil twists binds repressor only slightly better than non-supercoiled DNA. Negative supercoils should stabilise cruciform structures.

The extent of 'single strandedness' which is necessary to provide the results described here is unknown also but may be only a few nucleotides. Our results should not be interpreted as necessitating long stretches of random coil structure.

We anticipate that the nucleolytic scissions by the singlestrand specific nucleases are at the repressor binding site, as implicated by the repressor protection experiment (Table 1). But it may be that a neighbouring region is the site of attack and that the influence is transferred along the DNA chain. Experimental justification for the transmission of conformational stability (telestability) has recently been found (Burd, Wartell, and R.D.W unpublished) with the duplex block polymer  $d(C_{15}A_{15})\cdot d(T_{15}G_{15})$ .

That the lac operator may possess elements of single strandedness is consistent with the high degree of specificity of binding of the repressor since nonhelical DNA could provide substantially more characteristic sites for binding than helical DNA13.

This work was supported by the National Science Foundation. We thank Professor J. Dahlberg for determining the size of a DNA sample on polyacrylamide gels.

Note added in proof: Preliminary results show that the halflife for the S<sub>1</sub> nuclease nicked DNA-repressor complex is reduced from 20 min to approximately 10 min, thus explaining the lack of total abolition of repressor binding.

### QSOs of high redshift?

We have completed a series of observations at Jodrell Bank on the radio structures of a complete sample of OSO candidates identified from the Parkes ± 4° equatorial survey. Four sources are of particular interest in that they have properties which lead us to suggest that they may be QSOs of unusually high redshift.

At present we are not aware of any QSOs with steep radio spectra which have redshifts greater than 2.4; all those with higher redshifts have flat or concave radio spectra. (We use the spectral categories defined by Stannard<sup>1</sup>, except that the spectral index is determined at 1 GHz observed frequency

rather than 3 GHz emitted frequency.) It is of interest to consider the properties that QSOs with steep radio spectra and high redshifts may possess. In common with most of the known high redshift QSOs they would probably lack an ultraviolet excess2. A further property may be deduced from studies of angular diameter3,4 which suggest that, at high redshift, steep spectrum QSOs are likely to be compact, with angular diameters of less than a few arcs. Most of the flat and concave spectrum QSOs of high redshift have visual magnitudes between 18 mag and 19 mag. The studies of Setti and Woltjer<sup>5</sup> and Stannard<sup>1</sup> suggest, however, that any steep spectrum QSOs of comparable redshift will be, on average, about one magnitude fainter. One reason for the apparent lack of steep

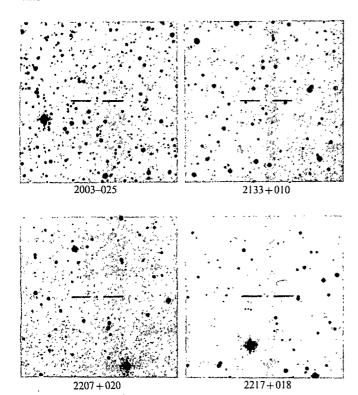

Fig. 1 Finding charts (approximate scale 10 arc s mm<sup>-1</sup>) reproduced from the red prints of the Palomar Sky Survey.

spectrum QSOs of high redshift may be that few QSO candidates fainter than 19.5 mag have been studied spectroscopically.

The Parkes 2,700 MHz survey of the  $\pm$  4° equatorial strip contains 341 sources above the completeness level of 0.35 Jy(1 Jy =  $10^{-28}$  W Hz<sup>-1</sup>m<sup>-2</sup>). We have used accurate radio positions measured at the Royal Radar Establishment, Malvern, to check the original Parkes identifications, and in some cases to propose new or revised identifications. One hundred of the sources can be identified confidently with stellar objects down to the limit of the Palomar Sky Survey prints. The radio structures of these QSO candidates have been studied at 962 and 1,666 MHz with the Mark II-III radio link interferometer at Jodrell Bank. Full details of these observations will be published elsewhere. Four steep spectrum sources were found to be essentially unresolved, and all have optical properties, which, from the discussion above, would be expected of high redshift QSOs.

The positions of the four QSO candidates are given in Table 1, and finding charts are given in Fig. 1. The properties of the objects are summarised in Table 2. They all have spectral indices equal to or steeper than -0.7, and none shows evidence of a low frequency cutoff. This suggests that the sources do not possess intrinsically compact structures. Three are completely inresolved in our interferometric observations and thus have argest angular sizes of less than 0.5 arc s. The fourth (2207 + 120) may possess extended structure in addition to a compact component giving rise to 70% of the total intensity. Visual

magnitudes for the sources have been estimated from the Palomar Sky Survey prints. All are 19.5 mag or fainter. Colour estimates have been provided by J. G. Bolton for almost all the QSO candidates in our sample. Three of the four sources discussed here are amongst the small number (only seven) found to have no ultraviolet excess. Another of the seven, which has a flat radio spectrum, has a redshift of 2.66 (ref. 7).

Table 2 Radio and optical properties of compact QSO candidates

Source	Radio spectral	Largest angular	Visual	Ultraviolet
	index		magnitude	excess
2003 - 025	0.7	< 0.5	19.5	No
2133 + 010	-0.7	< 0.5	20.0	Yes?
2207 + 020		$(\sim 1)$	19.5	No
2217 + 018	-0.7	≥0.5	19.6	No?

Individually, the properties of small angular size or optical faintness cannot be taken as strong evidence that a QSO has an unusually high redshift. When, however, these properties are combined with a steep radio spectrum and lack of ultraviolet excess, we consider that such an object may well have a high redshift. Optical spectroscopy on 2003-025 and 2207+020 has recently been reported by Strittmatter et al.8. They confirm that both objects have ultraviolet deficits, but are unable to assign redshifts. Despite this, we suggest that all four objects are worthy of further spectroscopic investigation.

### Change of pulse characteristics of the Vela pulsar with frequency

Below 2,000 MHz the average pulse profile from the Vela pulsar (PSR 0833-45) shows a single peak with a sharp rise and a more gradual decay<sup>1</sup>. At higher frequencies a broader and more complex pulse is observed, evidently comprising two distinct components<sup>2,3</sup>. Observations at 1,400 and 4,830 MHz made with the Parkes 64-m telescope in November 1972 to clarify this frequency dependence can also be related to some  $\gamma$ -ray observations made by Albats *et al.*<sup>4</sup> at the same time.

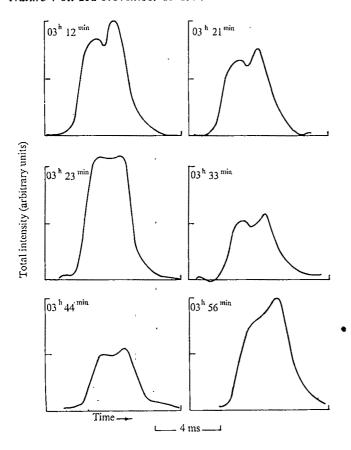

Fig. 1 Average 'total intensity' profiles measured at 4,830 MHz. Each profile is the sum of two integrations at orthogonal position angles of the feed. At each position angle 500 pulses were superposed. The times are Eastern Australian Standard Time on November 8, 1972.

Details of the radio observations are given in Table 1. A single receiver and linearly polarised feed were used at each frequency.

Figure 1 shows some examples of the 'total intensity' pulses measured at 4,830 MHz. The double structure is apparent, as is the time variability (over periods of a few minutes). Some of the variability must be intrinsic to the pulsar, since the relative amplitude of the two peaks also varies. Before the polarisation analysis was carried out the total intensity profiles were normalised.

Ideally, to determine which 4,830 MHz peak most nearly coincides with the 1,400 MHz pulse, simultaneous observations should have been made. But since the two receivers cannot be operated simultaneously the observations were made consecutively and connected by accurate timing measurements.

Table 1 1972 November observations of PSR0833-45*							
Date	Frequency (MHz)	Bandwidth (MHz)	System temperature (K)				
November 8, 1972	4,830	15	90				
November 15–19, 1972 (inclusive)	1,400	0.1	120				

\* Average pulse profiles were measured by superposing many pulses, using a time base operating at the Doppler-shifted pulsar frequency and a sampling rate of 1/400 period (0.223 ms). Such pulse profiles were formed at a number of different feed position angles and the linear polarisation parameters of the average pulse were computed. The measurements were made in pairs, one feed position angle being followed by the position angle orthogonal to it. The sums of such pairs of integrations yield the total intensity pulse.

Several times on each observing day the pulse arrival time was measured against a timing pulse from a caesium-beam clock. Each measurement was accurate to about one-half of a sampling interval, or about 0.1 ms. From the measured arrival times at 1,400 and 4,830 MHz, and from the pulsar's known position<sup>5</sup> and dispersion measure<sup>6</sup>, the barycentric period  $P_0$  and its time derivative  $\dot{P}$  were estimated. For JD 2441638.5 these were  $P_0=0.08922348324\pm7$  s and  $\dot{P}=1.2508\pm0.002\times10^{-13}$ . This value of  $P_0$ , together with the value<sup>7</sup> on JD 2441199.2 and one measured at Parkes on JD 2441934.5 (made available by V. Radhakrishnan and J. Brooks) yields values of  $\dot{P}$  averaged over several months before and after our observations. These are  $1.2477\times10^{-13}$  and  $1.245\times10^{-13}$ , both very slightly smaller than our estimate.

The 'arrival times' used in the estimates relate to the halfintensity points on the leading edge of the pulse. To test the

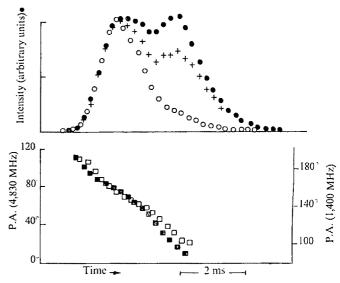

Fig. 2 Average pulse characteristics at 1,400 MHz (open symbols) and at 4,830 MHz (filled symbols). The crosses represent linearly polarised intensity at 4,830 MHz.

possibility that the second 4,830 MHz component more nearly coincides with the 1,400 MHz pulse, we added 1.8 ms—corresponding to the delay of the second component relative to the first—to the 4,830 MHz arrival time and repeated the calculation. There was no significant change in  $P_0$ , but P increased to  $1.256 \times 10^{-13}$ , thus widening the disagreement with the long-term averages. We therefore associate the first component at 4,830 MHz with the single 1,400 MHz pulse.

Figure 2 shows the average profile at 4,830 MHz with that at 1,400 MHz superimposed. The leading edges have been accurately aligned. The shapes of the leading edges and the form of the polarisation position angle 'sweep' at the two frequencies agree well. The position angle at the first 4,830 MHz peak also agrees to within a few degrees with the value extrapolated from lower frequencies. Thus the 4,830 MHz pulse may be represented as the sum of two components (Fig. 3), the first being similar to the 1,400 MHz pulse. The energies  $E_1$  and  $E_2$  of the two components are each equal to about  $20 \times 10^{-30}$  J m<sup>-2</sup> Hz<sup>-1</sup>.

Pulse variability makes it extremely difficult to estimate a meaningful absolute spectral index for frequencies above 4,830 MHz. Writing  $E_1 \propto f^{-\alpha}$  we find values of 2.2 or 4.8 for  $\alpha$ , depending on which measurements<sup>3,5</sup> near 8,000 MHz we combine with the present data. The relative spectral index is more easily estimated. The present results, together with those of Downs *et al.*<sup>3</sup>, indicate that  $E_2/E_1$  varies approximately at

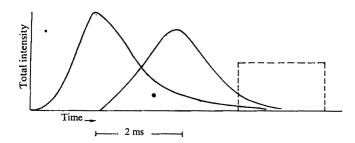

Fig. 3 The two pulse components at 4,830 MHz. The rectangle represents the arrival time of a possible γ-ray pulse as reported by Albats et al.4 The delay of the radio pulse due to dispersion has been removed.

 $f^{2.3}$ . The very much flatter spectrum of the second component suggests that a different emission mechanism is involved, but it is of interest that the position angle sweep through the whole pulse shows little frequency dependence.

Any pulses at frequencies beyond the radio domain might be expected to occur at the time of the second component. On November 16, 1972, Albats et al.4 attempted to detect pulsed  $\gamma$  rays in the 10-30 MeV range from the Vela pulsar. Figure 3 shows the temporal relation between the radio pulse and a possible  $\gamma$ -ray pulse that they report. It seems to lag behind both components of the radio pulse. The estimated uncertainty in our absolute timing measurement does not exceed 1 ms, and Albats et al. quote a similar uncertainty for their data. The time difference exceeds the sum of these uncertainties, but it is of interest that the  $\gamma$ -ray pulse more nearly coincides with the 'flatter spectrum' radio component.

We thank M. E. Ash, I. I. Shapiro and W. B. Smith of MIT Lincoln Laboratory for the use of their ephemeris of the Earth.

### New extragalactic variable sources from an 8-GHz survey

Studies of variable extragalactic radio sources have concentrated on sources with 'centimetre-excess' spectra, so that few sources without such spectra have been extensively monitored. We have used the NRAO 300-foot transit telescope at 2.7 GHz to make repeated, accurate observations of 48 sources selected by the Michigan 8-GHz survey without further bias towards any radio spectral type. Variability has been detected in two radio galaxies without centimetre excesses and every quasistellar source in the survey has now been observed to vary at some frequency.

We observed every 8-GHz survey source less than 1' in diameter that would not be significantly confused using the 4.7' resolution of the 300-foot telescope at 2.7 GHz. A threefeed system was used to determine declination pointing corrections at every source transit, so that flux densities could be measured with standard errors of  $\sim 0.03$  Jy from a single transit. The normalisation of the flux density scale among the seven observing periods between September 1972 and June 1974 was established to within 0.5% by observing ~200 nonvariable sources. Details of the observing and calibration procedures will be given by Kesteven and Bridle (in preparation).

Flux densities derived from different transits of a source within each of the seven observing periods have been averaged, as the flux density scatter between transits separated by only a few days is generally consistent with the errors computed for single transits. A  $\chi^2$  test was used to assess whether the scatter of the flux densities from different observing sessions is larger than expected from the errors in the individual measurements. We consider a source to be variable if the  $\chi^2$  probability that the observed scatter arises by chance is less than 0.1%, and possibly variable if it is between 0.1 and 1%. If some sessional flux densities were derived from only one transit the test was repeated deleting each such single observation in turn, and our assessment of source variability is based on the most mutually consistent data set. This procedure ensures that no source is considered variable on the evidence of a single discrepant transit which might have been affected by unknown instrumental effects.

The results for the 48 sources observed are summarised in Table 1. The flux densities are adjusted to the scale of Kellermann et al.3; the errors given for nonvariable sources do not include the uncertainty in normalising to this flux density scale as this does not affect our assessment of variability between the seven observing periods.

Twenty-one of the sources are variable at the 99.9% confidence level and three more at the 99.0% level; seventeen of these 24 are previously known variable sources. The measured flux densities of the five new variable and two new possibly variable sources are given in Table 2. Eleven previously-known variable sources did not vary significantly; the variable component(s) of these sources may make only a small contribution to the total flux density at 2.7 GHz or they may have been quiescent throughout the observing period (see Fig. 3 of Medd et al.4 for examples of such quiescence in variable sources).

The observations confirm the finding<sup>1,2</sup> that the stellar objects in the 8-GHz survey tend to be variable on time scales of a few years whereas the radio galaxies do not. Nine of the fifteen confirmed QSS are variable at 2.7 GHz with variability indices from 0.030 to 0.243, and the remaining six have all varied at one or more other frequencies (see Table 1). Thus all of the confirmed QSS in the 8-GHz survey are now known to be variable. We have also found 8 of the 15 stellar objects without measured red shifts to be variable at 2.7 GHz

with variability indices from 0.049 to 0.204, a range very similar to that exhibited by the confirmed QSS. Five further stellar objects in the survey are known to have varied at some other frequency. The only 8-GHz stellar objects not yet observed to vary are 0237-02 and 2335-02.

These results are consistent with those of other studies of radio-source variability (such as ref. 9) as all of the stellar objects in the 8-GHz survey have centimetre-excess spectra. The very high incidence of variability among stellar objects with such spectra (93%) suggests that nonvariable objects of this type are rare, if indeed they exist at all.

Our results for radio galaxies are more surprising. Of the ten radio galaxies observed, two (0111+02 and 1635-03) have centimetre-excess spectra and neither has yet been found to vary at any frequency. Unexpectedly in view of most earlier studies, two of the remaining eigh radio galaxies have shown significant variations at 2.7 GHz. These are 0034-01 (3C15) and 0240-00 (3C71). Hazard et al.10 found 0034-01 at 410 MHz to have three main components each ~2" in diameter, the outer components being ~10" apart. The innermost component coincides with the elliptical galaxy that is the identification. 0240-00 has 25% of its 2.7-GHz flux density in a component <1.5" in diameter11 located in the nucleus of the Seyfert galaxy NGC 1068. It has previously been suspected of being variable at millimetre wavelengths<sup>12</sup>. In both 0034-01 and 0240-00 at least part of the radio source lies within the associated galaxy, but the variable components do not dominate the

<sup>\*</sup>The mean flux density is given for sources that did not vary significantly at the 99% confidence level.  $\circ$  †See Table 2 for detailed flux density tabulation. †The 'variability index',  $V_{2,7} = (S_{\text{max}} - S_{\text{min}}) / (S_{\text{max}} + S_{\text{min}})$ , is a normalised measure of the amplitude of the observed variations.

high frequency spectrum as in the well known variable radio galaxies such as 3C84 (NGC1275). The variations observed in 0034-01 and 0240-00 are of correspondingly small amplitude, with variability indices of 0.058 and 0.071 respectively. It will be important to determine whether there are variable components in other multi-component radio galaxies like 0034-01, and to establish the location of such variable components within the radio structures.

Five of the six unidentified sources with centimetre excesses are also variable at 2.7 GHz, with variability indices that range from 0.047 to 0.305. The variability of these sources suggests that they are likely to be quasistellar objects.

We thank the Director of the National Radio Astronomy Observatory for providing observing time and the National Research Council of Canada for support. The NRAO is operated by Associated Universities Inc. under contract with the National Science Foundation.

### Infrared emission in R CrB type stars

Infrared emission has been observed in R CrB type stars and is considered to be the reradiation of the absorbed visual light by graphite grains1,2.

The lack of correlation between change of star brightness and infrared emission3,4 has been explained in terms of condensation of grains in discrete clouds escaping from the star in random directions. Under this condition we could observe infrared emission without any corresponding change in star brightness. In April and May 1972, however, the observed brightness of one R CrB star decreased about 6 mag, but no changes of infrared flux were observed.

We consider here a possible interpretation of this effect. It seems possible that in the escaped shell nuclei of grains might form in the shape of Platt particles. Such graphite particles with demensions from 3 to 30 Å will be like nonsaturated molecules, the more so as it is likely that a graphite structure with vacancies will grow up. In these

particles absorption is a quantum-mechanical process resulting from electron jumps between different Fermi levels. For quasi-metallic particles the longest wavelength will be absorbed by one electron, when it jumps from the highest filled to the lowest empty Fermi level. Its wavelength is given approximately by  $\lambda \approx 400L$ , where L is the dimension of the particles. Platt particles will re-emit photons isotropically which were absorbed from an incident beam with very small shifting to the red. These particles cause the extinction a few hundred times greater than classical grains with the same mass; however, they will not reradiate in the infrared region.

The growth of Platt particles to a size of order 10<sup>-7</sup> cm (by accretion C,  $C_2$  and so on, and perhaps coalescence) leads to the formation of the classical nuclei of grains. Further growth will form graphite grains with the radii between  $2 \times 10^{-6}$  and  $2 \times 10^{-5}$  cm whose re-emission in the infrared completely fits the observational data for R CrB and SY Sgr stars<sup>6</sup>.

It is possible that infrared emission is shifted in time relative to the light minimum by an amount appropriate to the necessary period of formation of the classical graphite grains. This time shift depends on the initial conditions of the escaped shell, particularly on the density • and velocity of escape. For that reason this time shift may be different for particular light minima.

This interpretation is confirmed by the fact that light polarisation of R CrB star observed by Coyne and Shawl<sup>7</sup> is strictly correlated with the light curve. At light minimum, and some time after, its light polarisation increases with the decrease of the wavelength which agrees with the behaviour expected for polarisation caused by Platt particles8. For the period before minimum, polarisation is considerably lower and its dependence on the wavelength indicates an origin from grains with relatively large sizes.

### Polarisation in the night sky at 5,300 A

We have presented observations1 of the linearly polarised intensity, pI, at 5,080 Å (that is, polarisation,  $p \times$  intensity, I), of radiation in the night sky. Contour plots of pI showed a displacement of the minimum of pI away from the antisolar point (ASP). A significant angular structure, and day-to-day variations were also evident. Here, we report observations of pI and of the orientation angle,  $\chi$ , of the polarisation plane of radiation at 5,300 Å in the night sky. Measurements have been taken since May 1973 with a photoelectric polarimeter at the University of Hawaii (J. L. Weinberg, unpublished). Several modifications have been made recently, the most important being the analog-digital conversion of data recording. Digitisation allows faster data reduction and improves measurement precision, which is now limited by instrumental polarisation and photon statistics.

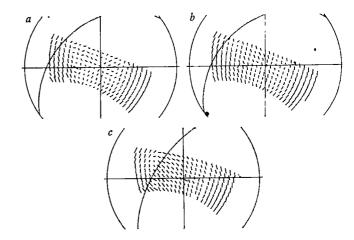

Fig. 1 Linear polarisation of the night sky at 5,300 Å. The diagrams are centred at the ASP. The north ecliptic pole is at the Vertical line, antisolar meridian; horizontal line, the ecliptic plane; dotted line, galactic equator. Part of the circle representing 90° solar elongation is shown. Each measurement is represented by a line with a length proportional to  $\log{(1+pI)}$ , where pI is polarised intensity in  $S_{10}$  (V) units. a, August 25, 1973; b, August 26, 1973; c, July 29, 1973.

Full data will be published elsewhere; here, we discuss 63 night of observation from May 1973-June 1974.

Our observations consist of regular measurements of th Stokes parameters, I, Q, and U, of the night sky radiation a 5,300 Å (half-intensity filter width 53 Å) at fixed altitudes or the N-S meridian. Meridian observations are preferable because they allow measurement of each region at its maximum altitude when the influence of tropospheric scattering is minimal Initially, we observed only on the 180° meridian at altitudes o 35°-75° at 5° intervals, using a 5° diameter field of view and ar integration time of  $\tau = 2$  min to ensure a high precision in the measured position angle,  $\chi$ , of the polarisation plane. For more complete coverage of the night sky, we now observed on both the north and south meridian, at altitudes of 35.0°, 41.9° to 83.3°, and 90°, again using a 5° diameter field of view but with an integration time of only 30 s. A reduction in  $\tau$  was necessar in order to maintain the same spatial resolution—about : square degrees. For  $\tau = 30$  s, the typical uncertainty in  $\chi$  is 6°small enough to allow the detection and monitoring of significan detail in the polarisation. The possible influence of tropospheric scattering is minimised by observing above an altitude of 35 (and on the N-S meridian). We also monitored tropospheric effects by observing a fixed set of points, all with a declination of 20.7°, at various altitudes. We found that at Haleakala tropospheric scattering at 5,300 Å is usually unimportant above an altitude of 35°. Occasionally though—for instance, during enhanced airglow activity—close examination of the data fo tropospheric scattering effects may be necessary.

Polarisation maps can be prepared from the data; these arplots of the polarised intensity vector in an ASP-centred diagram (Fig. 1). Maps of Q, U and pI ( =  $[Q^2+U^2]^{1/2}$ ) can also b obtained1.

The polarisation maps show several effects: first, sufficiently far away from the ASP (and from the galactic plane) the polarisation plane tends to be normal to the scattering plandefined by the Sun, the Earth, and the zodiacal dust particle This orientation can be expected if the dust particles are spherical or non-spherical and randomly oriented.

Second, within about 30° from the ASP, there are significandeviations from this orientation. They take the form of two polarisation patterns: pattern a, with relatively small values o pI (typically less than 0.8 S<sub>10</sub> (V) near the ASP), and with nearly random orientation of the polarisation plane (Fig. 1a); pattern i

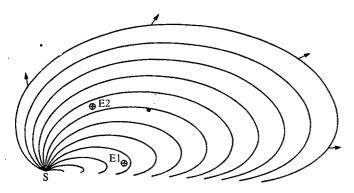

Fig. 2 Schematic representation of an expanding shock front from the solar wind. The Sun is at S, the Earth at two alternative positions, E1 and E2 (see text).

has pI values typically larger than 1.5  $S_{10}$  (V) near the ASP, with the polarisation plane tending to be normal to the ecliptic plane (Fig. 1b).

Third, a pattern usually persists for as long as a week, which was our typical useful observational period during a lunation, with only minor changes occurring in that pattern. At least one example of a sudden change was, however, observed, between August 25 and 26, 1973 (compare Fig. 1a and b).

Fourth, the influence of the Milky Way on the polarisation is seen clearly when the galactic equator crosses the ecliptic within about 30° of the ASP. There is a tendency for the polarisation vectors to be rotated normal to the galactic equator (Fig. 1c).

Fifth, the polarised intensity does not vanish at the ASP; that has already been established<sup>1</sup>.

The observed effects can be understood if the zodiacal dust is non-spherical and if, at distances from the Sun typically greater than 1 AU, it can have preferred directions of orientation, that is, be partially aligned. Observational evidence of the existence of appreciably non-spherical grains has been presented elsewhere (refs 1-3, and R. D. Wolstencroft, and J. C. Brandt, unpublished). The fact that at elongation angles,  $\epsilon$ , of less than  $90^{\circ}$  the polarisation plane tends to be normal to the scattering plane implies that close to the Sun the particles are more nearly oriented randomly. This conclusion is supported by the observations of Sparrow and Ney4, who detected no change in the zodiacal light at 90° elongation over a 4-yr period.

We suggest that the polarisation patterns, a and b (Fig. 1a and b) correspond to two states of particle orientation: an undisturbed state (Fig. 1b) in which the particles are partially aligned; and a disturbed state (Fig. 1a) corresponding to random orientation. We have suggested (ref. 1, and R. D. Wolstencroft and J. C. Brandt, unpublished) that the interaction of the dust with the solar wind plasma and with the interplanetary magnetic field, changes the orientation and the degree of alignment of the grains. Details of the theory of the interaction need to be established, particularly the way in which significant changes in grain orientation are produced sometimes in only one week, or less. Nevertheless, we can suggest models which relate the observed changes of the polarisation pattern to disturbances in the solar wind plasma of the magnetic field.

Consider the influence of the disturbed solar wind. As the shock front associated with a solar wind disturbance moves outward from the Sun and into the domain of grains which are usually aligned, an expanding region of disoriented grains forms in that domain (that is, at distances typically greater than 1 AU). Consequently, the polarisation pattern in the antisolar hemisphere changes from b to a (Fig. 1a and b). The effect of the zone of disoriented grains on the polarisation pattern depends on the position of the Earth. If the position is that of E1 in Fig. 2, evidently only part of the antisolar hemisphere shows a disturbed pattern. If the position is E2, the entire hemisphere is affected. But the angular size of the disturbed pattern also depends on the scattering function of the grains and may be

smaller than the size of the region in which the orientation of the grains has been disturbed. When the line of sight through the zone of disoriented grains becomes long enough, observable changes in the polarisation pattern will occur; it will occur a few days after the shock front has encountered the Earth. The change in pattern will be gradual and should be most noticeable close to the ASP where the particles beyond the front contribute relatively little to the polarised intensity.

Now consider the influence of regions of disordered magnetic field, which are associated with sector boundaries. As in the case of shock fronts from the solar wind we assume that the passage of the sector boundary disorients the grains. If the time needed for the particles to be re-aligned were greater than the time that occurred between boundary passages (typically one week) then the grains would be permanently disordered. The orientation of the polarisation within 30° of the ASP given by pattern B is inconsistent with permanent disorientation of the grains. When the sector boundary reaches the Earth we should see a sharp edge dividing the polarisation pattern into ordered and disordered zones (corresponding to patterns b and a, respectively). As the boundary moves past the Earth, this edge moves towards the ASP and into the morning hemisphere. For reasons related to the scattering function, already mentioned, the moving edge may not be well defined, however, and may therefore not be detected until it has come close to the ASP.

As the observed changes in polarisation patterns depend on the position of the Earth relative to the disturbances in the interplanetary medium, as well as on other factors (such as the scattering function of the dust), correlating pattern changes and events in the interplanetary medium is not a trivial task. In fact, we have not been able to attribute the sudden change between August 25 and 26, 1973, to any interplanetary event. We are not discouraged, however; if a clear correlation between pattern changes and events in the interplanetary medium were established, there would exist a unique method of observing and monitoring the interplanetary medium in regions as yet inaccessible to space probes.

### Arithmetic of ice ages

THE Milankovitch hypothesis is that glaciations occur when the Northern Hemisphere receives relatively little summer heat from the Sun, because of astronomical factors that alter the orientation of the Earth's axis and the eccentricity of its orbit. A new time scale for the ocean-bed record of the past eight glaciations is provided<sup>1,2</sup> by the magnetic reversal at the start of the Brunhes epoch, 700,000 yr ago. In addition, Vernekar's recalculated insolation tables3 are now available. For a popular account of climatic change4, I wanted to illustrate the opportunity thus provided, for a re-evaluation of the Milankovitch hypothesis.

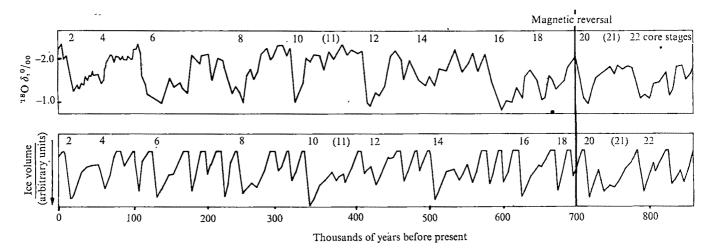

Fig. 1 Upper, measured oxygen-isotope changes in marine organisms from Fig. 9 of ref. 1; low points indicate a large volume of ice. They are plotted against depth in core and so the dating is uncertain except at the magnetic reversal 700,000 yr BP. Lower, ice volume derived by arithmetic as described in the text, from 50°N insolation data given in ref. 3 (inverted, arbitrary units).

An inspection of Vernekar's tables suggested that the crucial zone for summer sunshine was not at the Arctic Circle, as has often been supposed, but at 50°N. The theory of ice sheets growing from the bottom up<sup>5,6</sup> and the discovery of the English Channel glacier<sup>7,8</sup> fed from the seabed south of Ireland make this choice of latitude glaciologically plausible.

Suppose, now, that a decline in summer sunshine at 50°N below a certain level allows the volume of glaciers and ice sheets to grow in simple proportion to the deficit, while summer sun-

Dates in thousands of years BP.

shine above that level melts ice with a different proportionality. For the point of equilibrium I take 17 langley per day (1 langley = 1 calorie cm $^{-2}$ ) above the 1950 value of 847 langley per day. Glacial maxima or minima are then predicted at the dates when the summer insolation at 50°N crosses the +17 level.

Simple summing, by 1,000-yr steps, of the surpluses or deficits above or below +17 indicates in arbitrary units the extent of freezing or melting between the maxima and minima. With a melting rate of unity, a freezing rate of 0.22 gives a realistic curve for the most recent glaciation (the past 78,000 yr); melting the ice is easier than making it. The same proportionalitites are then applied over the past 860,000 yr. Finally, as surplus sunshine cannot melt ice that is not present, a limiting value for the reduction in ice volume can be assumed. The running totals then predict the amount of ice in the world. Figure 1 compares the resulting arithmetical curve with measurements of the oxygen-isotope ratios in marine fossils<sup>1</sup>, which are also thought to be proportional to the amount of ice in the world. Table 1 compares the dates of maximum glaciations

arrived at arithmetically, with the corrected dates deduced by Emiliani and Shackleton<sup>2</sup> who take account, as best they can, of variations in ocean-bed sedimentation rates.

Meteorological processes are so notoriously nonlinear that my assumptions are almost frivolous. The matches between the curves of Fig. 1 and the dates of Table 1 are very much better than they deserve to be unless the Milankovitch effect is indeed dominant. The arithmetical curve captures all the major variations and the core stages can be identified with little ambiguity. The defects include an excessive warm peak 170,000 yr ago, and excessive freezingin the more recent parts of corestages 11 and 21. On the other hand, the arithmetical curve registers two known events not conspicuous in Shackleton's oxygen-isotope curve, namely the cooling at 90,000 yr ago<sup>9,10</sup> and the warming at 100,000 yr BP required by the speleothem data<sup>2</sup>.

Other processes are at work, including the 2,500-yr oscillation<sup>11</sup> that correlates with <sup>14</sup>C production in the atmosphere, and hence with solar events rather than with the Milankovitch effect. Nevertheless the variations in summer sunshine available for melting the snow of the Northern Hemisphere plainly determine the first-order pattern of past glaciations. One can even put an order of magnitude to the process. A surplus of one langley per day above the +17 level, at 50°N in summer, will melt sufficient ice to change the oxygen-isotope ratio of oceanwater at a rate of 0.01% per thousand years.

Extrapolation of the curve gives a first-order forecast (Fig. 2) for the 'next' ice age, which began 5,000 yr ago and will end 119,000 yr from now. Broecker and van Donk<sup>12</sup> arrived at a broadly similar forecast by more general reasoning from the insolation predictions. This ice age looks like a relatively slow starter. The theory, though, is of widespread snow that fails to

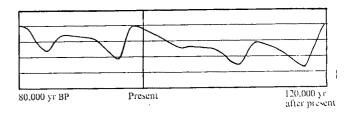

Fig. 2 Enlargement of the arithmetical curve for the most recent (Würm/Wisconsin) glaciation and an extrapolation for 120,000 yr into the future by the same arithmetical rules.

melt in the vicinity of 50°N in summer, so that large areas of North America, northern Europe and the USSR will have to be encrusted with ice sheets during the next few thousand years, to fulfil the expectations of Fig. 2.

I thank Dr N. J. Shackleton for suggestions and advice, and Professor H. H. Lamb for encouragement.

# New dates from the Ethiopian plateau volcanics

INTERPRETATION of geological events in Ethiopia has been severely limited by the lack of isotopic age data from the plateau volcanics. Volcanism was thought to have begun in the Eocene -an idea based chiefly on ages from the Blue Nile Gorge basalts<sup>1</sup>. These basalts have been resampled and ages of 23 to 27 Myr determined<sup>2</sup>. Recent research involving the measuring and sampling of volcanic profiles on the Western and South Eastern Ethiopian Plateaus, has made it possible to sample the basal flows which immediately overlie Mesozoic sediments. We report here nine new K-Ar dates from the Mugher, Adigrat, Garamullatta, and Jijiga profiles (Fig. 1.) The data are presented in Table 1 together with brief petrographic descriptions. All

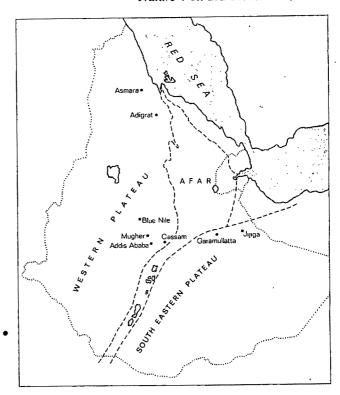

Fig. 1 Profile locality map of Ethiopia.

samples contain up to 12% intersertal glass; whole rock samples were analysed. The errors quoted are at the 60% confidence limit and based on replicate analyses.

The ages are striking both in their stratigraphic consistency and in the general similarity between profiles. Although it may be argued that they do not represent the oldest volcanics of the Ethiopian volcanic episode, nevertheless they do indicate that a considerable part of the plateau sequence is very much younger

30948		Basal flow 1.07		0.8451	78.7	19.8±0.7 Porphyritic basalt. Clusters of twinned, zoned plagioclases, pyroxenes and rare olivines in a fine matrix of similar composition. Less abundant opaque ore. Approx. 10% greenish-brown glass.					

than originally inferred. This is in good agreement with the new Blue Nile data, quoted above, and with an age of 20.9 Myr from the Cassam sequence3.

These K-Ar data cast considerable doubt on the theory that the volcanism began in the Eocene or early Oligocene4 since none of the ages so far obtained exceeds 30 Myr.

# Possible environmental index in tropical reef corals

PRELIMINARY results from a mineralogical study indicate that hermatypic corals may preserve in their skeletons a continuous record of noncarbonate sediments that were suspended in the waters in which they grew. Studies of coral structure, skeletal chemistry, and skeletal mineralogy1-6 have tended to neglect the significance of this trapped material. Our findings suggest that any comparison between the abundance of trace elements in corals from different areas may be questioned, as may those studies which suggest that large amounts of silica and aluminium are incorporated in skeletal carbonate.

This study was restricted to noncarbonate detrital fractions in the skeletal cavities of live, tropical reef corals which were free of macroborings filled with sediment. Specimens were from the eastern coast of the United States, the Gulf of Panama, and the barrier reef off Belize. They were prepared by coarse crushing freshcut, weighed coral fractions; dissolution at room temperature and pH 11 in ethylenediaminetetraacetic acid (EDTA)<sup>7</sup>; treatment with 30% H<sub>2</sub>O<sub>2</sub> to remove oxidisable organic material; drying and weighing of the residue; and then mounting the residue on glass slides for X-ray diffraction analyses. Mineral components were identified using standard analytical techniques8. Annual radial density bands, recorded in X radiographs<sup>9,10</sup>, were used to estimate growth increments in coral sections (Fig. 1).

Detailed microscopic examination of both freshly broken surfaces and surfaces etched with acid revealed some skeletal cavities which had been capped with a dissepiment after they had been partially filled with detrital material (Fig. 2). The dissepiments were commonly arched to accommodate trapped sediment, indicating that the polyps were alive when the sediment entered the skeletal cavities. As coral polyps can normally reject particulate material which is smaller than silt11, the sediment probably entered the skeletal cavities when the polyp was damaged or destroyed, and became sealed into the skeleton after polyp regeneration or recovery of a segment of the coral

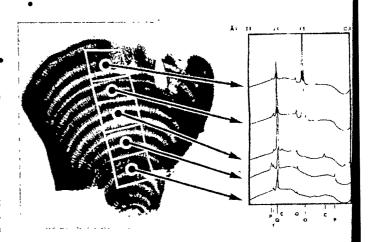

Fig. 1 X radiograph of Pavona gigantea showing variation in composition of noncarbonate detrital fraction relative to annual paired light and dark density bands. Note the appearance of gibbsite (4.85 Å) approximately six years ago. C, chlorite; T, tale; G, gibbsite; Q, quartz; F, feldspar.

colony. This type of material, however, was not found embedded in the skeletal carbonate matrix.

X-ray diffraction analysis of residue in specimens from the eastern United States showed the mineral suite: chlorite gibbsite, illite, kaolinite, montmorillonite, quartz, talc, and several feldspars (Table 1). As considerable mineralogica variation occurs in detrital material from corals of the sam species, the mineral suite is not species specific. It is, howeve related to the character of suspended or resuspended emateria

Table 1 Amount and composition of noncarbonate detrital material in corals

in the surrounding water masses<sup>12-14</sup>. No evident chronological patterns were observed in the mineralogical composition of this residue.

Residues from the Panamanian and Belizean corals include gibbsite, quartz, and several feldspars. These samples show that gibbsite (Al<sub>2</sub>O<sub>3</sub>) was introduced at the same time as the total amount of residue increased. The occurrence of gibbsite in the Panamanian specimen (Fig. 1) correlates in time with the start of a housing development in the Pearl Islands (P. W. Glynn, personal communication).

The type of noncarbonate detrital material in coral skeletons, therefore, may be dependent largely on spatial and temporal variations in the composition of sediment suspended in waters in which the corals lived. Thus, major changes in the kind of residue throughout the skeleton of a coral colony are probably the result of past changes in the character of suspended detritus.

Changes in the concentration and composition of trapped -detritus should be included in baseline studies because suspended -material is part of the total environment of a coral colony. Environmental interpretations could become more meaningful if mineralogical changes of trapped, suspended material were considered together with elemental distributions in coral skeletal carbonate. Detrital aluminosilicates are associated with many ecologically important trace elements<sup>15</sup>, so that any analytical scheme must consider the possible presence of detrital minerals if the calculation of partition coefficients is to be significant. • Cechniques for the separation of this detrital material must secessarily be chemical, because of its disperse nature in primary keletal cavities. Furthermore, the techniques should be lesigned to prevent the release of adsorbed or included metal ons from the detrital minerals.

Previous elemental chemical analyses must be interpreted vith caution in cases in which the presence of terrigenous detritus was not noted. Early coral-skeletal studies concen--rated on the major elements traditionally associated with the arbonate framework (Ca, Mg). A few trace metals were also envestigated, but little real attention was paid to them until it vas demonstrated16 that oxides of Fe, Al, and Si, in addition to •nost of the trace metals found in seawater, are present in coral keletons. There have been attempts to calculate partition or Mistribution coefficients for these elements<sup>5,8</sup>. Our work, and that of others16, suggests that most, if not all, Fe, Al, and Si, along with some alkalis and alkaline earths reported in coral

heads, are attributable to detrital aluminosilicates and other detrital minerals, rather than to material incorporated in the skeletal carbonate.

Coral samples were donated by P. W. Glynn, R. F. Perkins and F. T. Vernberg. We thank P. W. Glynn, J. W. Wells and W. A. Oliver for discussion and advice, and Mr W. R. Brown for operating the scanning electron microscope. Research was supported partially by Smithsonian Research Funds.

# Radiation dosage associated with ball lightning

A BALL lightning event occurred in a house in North Berkshire on May 8, 1970; here we report subsequent investigations using thermoluminescent dating techniques. According to some theories1-4 matter close to the path of such an event may experience a radiation dose of order 1 to 1,000 rad. Since the house was built of brick and only 25 yr old, it seemed possible that the mineral inclusions in the brick would exhibit a level of thermoluminescence (TL) significantly in excess of the level resulting from the annual radiation dosage received from the uranium, thorium and potassium contained as impurities in the clay of the bricks themselves.

The material tested was supplied by Ashby and Whitehead3. Cores (mostly around 30 mm in length) were taken from bricks around the doorway through which the ball lightning is reported to have passed (cl, 2, 4 and 7 of Fig. 1) and a series of controls well displaced from the event were added to the collection (c3, 10 and 12 of Fig. 1). Radioactive analysis of the clay (by alpha counting in the case of uranium and thorium, and by flame photometry in the case of potassium) indicated

that those crystalline inclusions which are free of self-radioactivity, such as quartz<sup>6</sup>, would experience an annual dosage of a little under 0.5 rad, thus accumulating TL equivalent to 12 rad since the bricks were fired.

In the measurement procedure<sup>5</sup> particular care was taken to suppress 'spurious' TL that was liable to show itself in the 275° C region of the glow curve; in addition to the utilisation of oxygen-free nitrogen, the grains were coated with silicone oil using an aerosol spray. The very low concentration of crystalline material in these bricks, ( $\sim 1$  to 2%), excluded the usual pretreatment of the sample by etching in hydrofluoric acid (this limits the sample to quartz and so ensures that the estimate of natural dose-rate is accurate). Radioactive analysis of an

<sup>\*</sup>Since some of the crystalline extracts were small only one method of TL analysis was attempted on each sample.

extract indicated that at least some of the crystalline minerals in the sample had an internal content of uranium and thorium even if the quartz present did not. A rough value of about  $0.15\,\mathrm{rad}\,\mathrm{yr}^{-1}$  was estimated for the resulting extra annual dosage, adding a possible 3 rad to the calculated accumulated dose in the cores.

As well as the conventional high temperature TL analysis<sup>5</sup> we investigated the sensitivity changes of the 100° C quartz peak<sup>6,7</sup> under the combined effect of radiation plus heating to 500° C. A similar heating of freshly annealed geological quartz causes no sensitivity change, nor is there any change if the sample is irradiated and the TL induced allowed to decay away at room temperature (the storage halflife is about 145 min). But if the sample is heated to 500° C there is an increase in sensitivity which is proportional to the size of the 'pre-dose'-the radiation dose received between the annealing

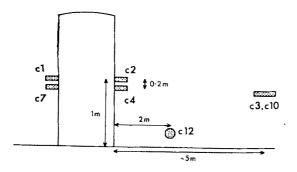

Fig. 1 Location of core samples.

and the heating to 500° C. In the present application we are concerned with the natural pre-dose that has been received by quartz in the brick between firing in 1945 and laboratory analysis in 1970.

The higher values of the estimated dose obtained by the high temperature method reflect the limitations on accuracy of this approach when only small amounts of sample are available (Table 1). The agreement between the predicted dose of 12 rad for quartz in the control cores and the observed pre-dose values (averaging at 13 rad) is satisfactory. The variations are probably due to the difficulties in estimation of the initial sensitivity values appropriate to quartz only. In the supposed 'hotter' doorway cores, though the average dose is slightly higher at 15.5 rad, the difference from the controls can hardly be treated as significant. If a ball lightning dosage occurred it would seem to be less than 5 rad in magnitude.

The model of ref. 1 would require a ball lightning event of less than 105 J at 2 m to produce such a dose and the model of ref. 3 would require an energy content of less than 2×10<sup>3</sup> J (less than  $2 \times 10^{-11}$  of antimatter).

This work should not be treated as in agreement or otherwise with another TL study<sup>8</sup> of possible effects of a ball lightning event in 1846. The author of ref. 8 was unable to detect any dosage in a damaged church steeple made of stone. Even the upper limit of 1,000 rad quoted earlier would be barely detectable in the face of the geological dose that the TL of such stone would record. We also feel that comments on the use of TL stored in the 110° C peak as an indicator of high dose radiation history should be read with the knowledge of the shortness of the peak's halflife. Even a delay of 1 d between event and TL measurement will reduce the peak intensity by a factor of around 1,000. But the sensitivity changes due to the pre-dose mechanism are stable over millennia.

We thank the Nuffield Foundation for support.

# New type of smectic mesophase?

4-Cyano-4'-octylbiphenyl (NC.C<sub>6</sub>H<sub>4</sub>.C<sub>6</sub>H<sub>4</sub>.C<sub>8</sub>H<sub>17</sub>) is a bipheny derivative of considerable technological interest since it forms colourless, stable smectic phase which exists at room tempera ture (21° C to 32.5° C). The corresponding ether 4-cyano-4 octyloxybiphenyl (NC.C<sub>6</sub>H<sub>4</sub>,C<sub>6</sub>H<sub>4</sub>,OC<sub>8</sub>H<sub>17</sub>) forms a similar smectic phase at a higher temperature range (54.5° C to 67° C Preliminary studies suggested that the smectic phases of thes compounds are not miscible with any recognised type of smect phase. Subsequent investigations (unpublished work by G.W.G have shown, however, that they are both miscible with a number of 'authentic' SA phases.

The X-ray diffraction photographs of the smectic phases c the two biphenyls are similar and are of a novel type. They bot consist of a sharp inner reflection and two diffuse outer refle tions as shown in Fig. 1. All smectic phases previously studie

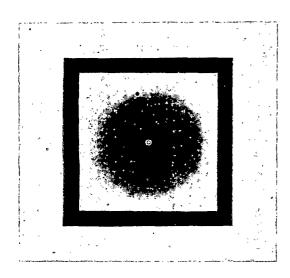

Fig. 1 The X-ray difraction pattern of 4-cyano-4'-octylbiphenyl, taken at room temperature with a flat plate camera. The sample was contained in a Lindemann glass tube (of diameter 0.1 mm). No specific measures were taken to orientate the sample and the partial ordering apparent occurred spontaneously. The innermost sharp reflection corresponds to a repeat distance of 31 Å. The two diffuse reflections correspond to ranges of repeat distances centred on 8.6 Å and 4.3 Å.

have given X-ray diffraction patterns which fall into one of the three categories (listed by de Vries² as types  $\alpha$ ,  $\beta$  and  $\gamma$ ). In all of these there are sharp inner rings corresponding to the smectic layer thickness. In type  $\alpha$  patterns there is one diffuse outer reflection, in type  $\beta$  there is one sharp outer reflection and in type  $\gamma$  there are three sharp outer reflections.

In the diffraction pattern of the biphenyls, the outer diffuse reflection corresponds to a d spacing of 4.3 Å and is at more or less the same position as the single diffuse reflection given by previously studied  $S_A$  phases (all of which are essentially conjugated aromatic systems of the general type p-X.C<sub>6</sub>H<sub>4</sub>.A = B.C<sub>6</sub>H<sub>4</sub>.Y-p). We note that the diffuse reflection characteristic

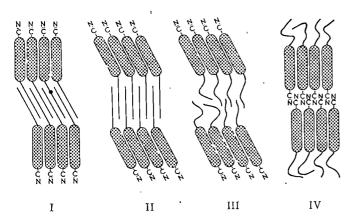

Fig. 2 Diagrammatic representations of possible alternative models for the smectic phases of cyanobiphenyl derivatives. I, Simple model featuring fully extended, interdigitated alkyl chains; II, model incorporating tilting of the biphenyl groups, which may be necessary to reduce the repulsive dipole-dipole interactions between the CN groups; III, model in which the alkyl chains are disordered and only partially interdigitated; IV, alternative model incorporating disordered alkyl chains where the two sheets of molecules in each layer are held together by the electrostatic interactions between the interdigitated CN groups in the centre of the layer.

of fluid hydrocarbon chains is found at a slightly lower angle, corresponding to a spacing of 4.5 Å or 4.6 Å, and no subsidiary maximum is discernible at this position in the diffraction pattern. The origin of the inner diffuse reflection is not apparent to us at this stage. The inner sharp reflection corresponds to a spacing of 31 Å, which is to be compared with the length of approximately 22 Å for the fully extended molecule. Some form of double layer structure is clearly mandatory. A number of possible models for the packing arrangement which have the correct layer thickness are shown diagrammatically in Fig. 2. All of these have layers of a sandwich construction. In model I the alkyl chains are fully extended and interdigitated. One questionable feature of this model is the juxtaposition of the CN groups. The bond dipole moments of these are appreciable (we would expect a value of about 4 debye units) and perhaps model II, which would reduce repulsive dipole-dipole interactions, is preferable. There is also the possibility incorporated into model III that the alkyl chains are disordered—which would reduce or remove the need for interdigitation. In the final model, IV, it is suggested that it is the interactions between the -CN groups, rather than between alkyl chains, which hold the two sheets of molecules together within the layer. It is hoped that this matter will be resolved (and the structural features which give rise to the two diffuse rings found) by our current investigations using mesophase samples oriented in a magnetic field and by extrapolating from the structures of the crystalline solids.

Optical studies by Gray and Harrison have indicated that both mesophases are uniaxial and only in the case of model IV are the individual layers uniaxial. Models I-III may, however, not be ruled out on this account because they would give uniaxial phases also if there were no correlation of the tilt directors from smectic layer to smectic layer.

# Orientation perception by children

In a series of publications Bryant<sup>1-3</sup> has advanced the interesting idea that children's perceptual processes in the early years are characterised by an absence of absolute codes and an exclusive reliance on relative codes. Much of this work involves the perception of orientation of lines: in a successive discrimination task (that is one in which the choice stimuli are presented after the standard has been withdrawn) children below the age of 5 yr have been found able to distinguish horizontal from vertical lines but not oblique lines from their mirror-image. Bryant suggests that children adopt a binary match-mismatch code, which tells them whether lines parallel each other or not. Horizontal and vertical lines can be matched with the framework of the plaque on which they are presented and coded accordingly; oblique lines, however, merely produce a mismatch signal in such a comparison. Thus the young child cannot as yet code orientation in an absolute sense and instead requires the help of features of his environment with which the stimuli can be compared.

It follows from such a view that even oblique lines ought to be discriminated correctly by young children when the task is a simultaneous discrimination situation. In such a situation the standard is presented together with the choice cards, so that, according to the match-mismatch hypothesis, the child can code the orientation of the correct line as being parallel with the standard. In simultaneous comparisons, near-perfect performance should therefore occur, even when the discrimination involves oblique lines. Bryant's studies seem to confirm this; we have, on the other hand, not been unable to replicate his

Our data were obtained by four groups of postgraduate students in successive years between 1970 and 1973, using identical methods and thus representing four replications. The 114 subjects (mean age 4 yr 5 months) were seen individually in a room at the nursery school which they attended, and presented with 4 inch square white cards on which 3 inch long black lines were drawn. There were two stimulus conditions, involving discrimination between a horizontal and a vertical line and between two oblique lines respectively, and two test conditions, that is, simultaneous and successive discrimination. Subjects served under all four conditions, receiving eight trials under each.

An analysis of variance of the error scores obtained by the whole group shows highly significant effects for stimuli (F= 88.68, P < 0.001), for test conditions (F = 69.96, P < 0.001), and for the interaction between these two terms (F = 24.58, P <0.001). It seems that the children found the horizontal-vertical discrimination considerably easier than that between oblique lines; that they performed very much better in the simultaneous than in the successive discrimination test; and finally, and most important, that the oblique stimuli were difficult under both conditions (see Table 1).

Table 1 Mean number of errors (max. 8, chance level 4)										
Stimuli	Simultane Mean	ous task s.d.	Successive task Mean s.d.							
Horizontal-vertical Obliques	1.10 3.17	1.48 2.01	3.10 3.89	1.80 1.59						

It is thus apparent that even when the standard card and the two choice cards were presented at the same time, the children were unable to discriminate among obliques. The presence of a stimulus for matching purposes was of little help in judging similarity, whereas no such difficulty arose in the discrimination of horizontal and vertical lines. Exactly the same pattern of results emerges when each of the four sets of data obtained in different years is analysed separately.

These results thus fail to confirm those reported by Bryant. It is not clear what factors may be responsible for the discrepancy, but taken in conjunction with the failure by Fellows and Brooks<sup>4</sup> to replicate another deduction from Bryant's theory, namely that children should be able to discriminate obliques in a successive task when the lines are presented within a diamond-shaped framework, it becomes apparent that reservations are necessary in accepting the match-mismatch explanation. It seems rather more likely that children initially have an absolute difficulty in coding oblique lines that is not overcome by the provision of parallel lines in the environment.

# Diapause potential in tropical flesh flies

FLESH flies (Diptera: Sarcophagidae) of the temperate region use the short, cool days of late summer and early autumn as a reliable cue to signal the advent of winter1,2 Flies may enter an overwintering pupal diapause in August, and the adults will not emerge until the following May2. Tropical flies, by contrast, are not exposed to a regularly occurring season of lethal temperatures, and flesh flies from Nairobi, Kenya, have been reared outside throughout the year without the occurrence of diapause (D. L. D., unpublished). Yet four species from equatorial Africa that have been examined, Sarcophaga inzi, S. monospila, Poecilometopa punctipennis and P. spilogaster, have all demonstrated the potential to enter pupal diapause. During diapause in both the temperate1,2 and tropical species, pupal development is halted at the early phaenerocephalic stage.

Colonies of experimental flies originated from wild females, and diapause experiments were carried out within the first year of laboratory rearing. Larvae from single females were reared in separate packets of beef liver2 P. spilogaster, a species collected in Nairobi (1°S), was examined most extensively.

Induction of diapause is temperature dependent. If the larvae and pupae of P. spilogaster are maintained at temperatures of 20° C or more, development proceeds without interruption (Fig. 1a). At 18° C, a few pupae enter diapause and as the temperature decreases the incidence of diapause increases. Diapause is not, however, an immediate reaction to the temperature experienced by the phaenerocephalic pupa. The transfer of young pupae to lov temperature does not result in diapause. The abilit to enter diapause is programmed during larval life. Maxi mum diapause response is obtained by cold exposure throughout larval life. A decrease in the duration o cold exposure (15° C) received by the larva decrease the incidence of diapause (Fig. 1b). If more than th first 2 d of larval life are spent at 25°C, the diapaus response is reduced to less than half the maximal res ponse. During July and August, the coldest month in Nairobi, mean daily temperatures are frequently low as 15-18°C; however, for induction of diapause series of 1-2 weeks of cool days would have to occur direct succession. An interruption by several warm day could avert the diapause. Although an accumulation of sufficient cold days for diapause induction occurs only rarely in Nairobi, at higher elevations within 20 km Nairobi, conditions that could induce diapause occu annually.

Unlike the temperate species, which react strongly photoperiod2, the tropical species seem to be uninfluence daylength for diapause induction. Differences coul

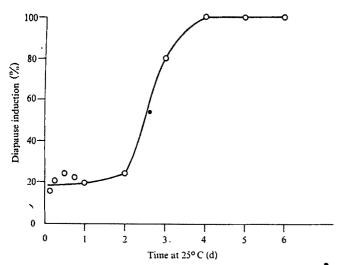

Fig. 2 Percentage of *P. spilogaster* that terminate diapause when transferred from 15° C to 25° C for different periods of time and then returned to 15° C. Pupae were in diapause 10 d before exposure to 25° C. Each point represents 25 pupae.

not be established among flies reared under daily photoperiods of 1, 10, 11, 12, 12.25, 12.50, 13, 15 and 24 h. Since seasonal variation in daylength is only 7 min in Nairobi, the results are not surprising.

Termination of diapause is temperature dependent in both temperate<sup>2</sup> and tropical flesh flies; spontaneous termination of diapause occurs later at lower temperatures. At 18°C, diapause in P. spilogaster lasts 72.6  $\pm$  2.9 d (mean  $\pm$  s.e., n=108), at 15° C 100.9  $\pm$  2.2 d (n=268), and at 12° C 234.6  $\pm$  6.8 d (n=207). Flies from the two regions, however, do differ greatly in their rate of response to favourable temperatures. If young diapause pupae of a species from a temperate region are transferred to 25°C, more than 100 d may elapse before diapause is terminated2. If diapause pupae of P. spilogaster are transferred from 15° C to 25° C, adult development can be observed within 3 d. The amount of exposure to 25° C required for diapause termination for P. spilogaster is seen in Fig. 2. In this experiment, pupae were exposed to 25° C for varying periods of time and were → then returned to 15° C; 4 d at 25° C was sufficient for diapause termination in all pupae. The difference in the ability to terminate diapause between flies of the two regions is a reflection of the environmental conditions to which each is exposed. The temperate region winter is a predictable event of long duration. The tropical seasons are less predictable. Years may go by without the species entering diapause. If the fly does enter diapause during a brief cold period, it is not committed to a long period of dormancy and can react immediately to a stimulus of higher temperatures.

That diapause has been observed in all four Sarcophaginae examined suggests that the potential for diahause may be common among the tropical species. The Sarcophaginae are thought to have originated in the ropics and subsequently spread to the temperate regions3. The necessity for diapause increases with distance away rom the equator, and the temperature dependency of tiapause becomes supplemented with photoperiodic cues <n the temperate region.

I thank Professor Jan de Wilde for his enthusiastic upport and NIH-NIAID for a postdoctoral fellowship.

# A fly's leap from paralysis

THE first temperature-sensitive paralytic mutant of Drosophila melanogaster, parats, was isolated four years ago1-3. The mutation was mapped as a point at 53.9 on the X chromosome<sup>4</sup>. The present day stock of parats moves normally at 22° C, but is paralysed within 10 s at 29.5° C. Paralysis is usually complete. The legs are held close to the body causing the fly to lie on its back or side. When returned to 22°C the fly recovers its mobility within 5 s. A much slower and less complete recovery occurs when the flies are left at 29.5° C (ref. 4). Only after 30 min are they able to walk and after 2 h a few flies can be induced to fly by shaking their container. The mutation has been shown to act in a regionally autonomous fashion within the head and thorax5.

By genetic and pharmacological means, activity can be elicited from parats flies at temperatures which would otherwise paralyse them. Augmented inhibition is suggested as a possible cause for this type of paralysis.

Our work concerns the interaction of para's with Hyperkinetic<sup>1</sup> (Hk<sup>1</sup>), another sex-linked mutation and the pertinent behaviour of this mutant is its response to movements nearby<sup>6</sup>. When waved at by hand it usually jumps and often tumbles. In our laboratory, Patrick Wong discovered that the fly responds similarly to a high intensity, high frequency stroboscopic light7. High speed motion picture films show that the take off and flight are abnormal8.

While hand waving seems to elicit a few jumps from Hk1 para ts flies at 22°C, these double mutants do not respond to this stimulus after they have been paralysed at 29.5° C. Hk1 parats flies, however, usually respond to the strobe light at 22° C and a few jumps can even be elicited after they have been paralysed at 29.5° C.

Hk1 parats flies did not respond under the high levels of heat and light emitted by the lamps used for high speed photography. Fortunately, flies carrying mutations which produce yellow cuticle (y) and white eyes (w) (ref. 9) together with Hk1 and parats (that is, y w Hk1 parats) were very responsive. Figure 1 is a photographic sequence of a y w Hk1 parats fly responding to a flashing light at 29.5° C. The first frame shows the paralysed fly lying on its right side facing away from the camera. After the flash, the fly pushes off with the midlegs and beats its wings twice before leaving the field of view. Other sequences show as many as seven wing beats. Normally Hk1 parats and y w Hk1 parats flies recover their mobility over a prolonged period, just as parats flies do. Yet at each instant from the time that paralysis is first induced, these flies retain the competence to see and to respond.

The light-induced escape from paralysis is short lived. The fly travels 2 or 3 cm and falls down in a paralysed state again. Furthermore, the response is often incomplete. The fly may push off with its midlegs, simultaneously lifting and spreading its wings only to return its wings to a resting position in midflight. The extension of the midlegs may also be incomplete: the femurs extending while the tibias remain folded. Such blocks in the jump and flight response have not been seen in wild type or Hyperkinetic flies and are therefore probably caused by the para's mutation.

Table 1 shows that the capacity of the  $Hk^1$  mutation to make the parats mutant jump at high temperature is greatly enhanced by the w mutation<sup>10</sup>. w Hk<sup>1</sup> para<sup>ts</sup> flies respond to both flashing

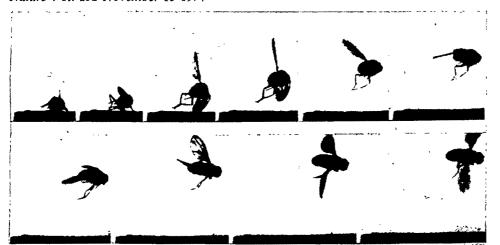

Fig. 1 The response of a y w Hk<sup>1</sup> para<sup>ts</sup>/Y fly to flashing light at 33° C. The sequence was recorded at 400 frames s<sup>-1</sup> in 5,500 lux illumination. 100 light flashes s<sup>-1</sup> were delivered by a Grass PS2 photostimulator at intensity setting '8'. The PST2 lamp and reflector were placed 20 cm from the fly. Paralysis was complete before stimulation.

light and movements. There is no indication that the mobility of  $w Hk^1 para^{ts}$  flies is greater than that of  $para^{ts}$  flies at elevated temperatures. Rather the added mutations seem only to sensitise the flies to visual stimuli.

Obviously, the sensory, neuronal and muscular elements involved in seeing, jumping and flying are functional. A degree of motor competence in paralysed para<sup>ts</sup> flies has also been demonstrated previously by the production of leg jerks through electrical stimulation of the cervical connectives<sup>11</sup>. On the other hand, the temperature-induced paralysis may be caused by abnormally high levels of inhibition of elements innervated by inhibitory neurones. When the light reaching the sensory cells is increased by the w mutation<sup>12</sup>, and the motor system is genetically primed by the Hyperkinetic mutation, certain visual stimuli elicit strong signals which override inhibition and call forth the high priority response of escape<sup>8</sup>.

Picrotoxin specifically blocks the action of  $\gamma$ -aminobutyric acid<sup>13</sup>, a probable inhibitory transmitter in insects<sup>14–16</sup>. Thus it may also prevent temperature-induced paralysis from occurring in  $para^{ts}$  flies.

Ten males, 4–5 d old, of each genotype, were placed individually into 8 cm  $\times$  2 cm vials, which were then laid on a white background. Each fly was subjected to quick horizontal passes of the hand about 5 cm above the vial, or light stimuli, each consisting of 10 flashes of 0.01 s duration, produced by a Grass PS2 photostimulator. At settings '4' and '8', the peak luminous intensities of the xenon lamp are stated to be about 2.2  $\times$  10's and 2.4  $\times$  10's candlepower. The lamp and reflector were placed 15 cm above the vial. Ambient intensities of illumination from overhead fluorescent fixtures were 700 lux at 22  $\pm$  1° C and 350 lux at 29.5  $\pm$  0.5° C.

Injections of picrotoxin elicited a random activity in para<sup>15</sup> and wild type flies at 22° C. Low concentrations caused the normal activities of the flies to be carried out in a shakey, uncoordinated manner. Higher concentrations increased the activity of the fly and abolished all coordination. The behaviour of all flies was not identical, but in various individuals, movements of the head, antennae, proboscis, wings, halteres,

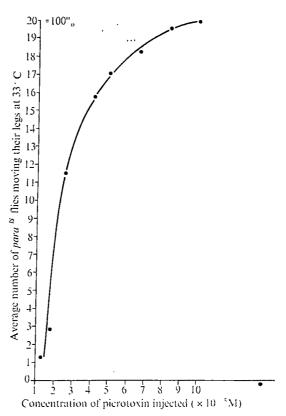

Fig. 2 Effect of picrotoxin on leg movements of para's flies at 33° C. Male and female para's flies, 3-24 h old, reared at 17° C were immobilised on a cold plate!8 and injected in the ventral posterior abdomen with about 0.25 µl of picrotoxin in Drosophila Ringer's¹º or Drosophila Ringer's alone. The dissecting scope lights were fitted with small water chambers to reduce heat. Uninjected control flies were kept cold for the same period. Two lots of 10 injected and 10 uninjected flies were placed in four covered thin plastic dishes²º. At 22° C they recovered from the cold until at least 80% of the uninjected flies were able to stand (4-6 min). The dishes were then transferred to a water heated observation chamber. The interior of each dish rose from 22° C to 33° C within 220 s. From 250-600 s, the number of flies able to move even a leg segment was noted at 50 s intervals. Other types of movements were not monitored. The average number of flies moving their legs is recorded on the graph. Over 90% of uninjected and Ringer's injected flies lay in a state of paralysis. In the same conditions, wild type Oregon-R flies were not paralysed, but did tend to stand still, walking and preening infrequently.

abdomen and legs were seen. We assume that these activities were the result of a blanket disinhibition of many parts of the nervous system which generate motor activity. These uncoordinated movements of parats also occurred, albeit less vigorously, at 33° C. The number of flies able to move their legs increased with increasing concentrations of the picrotoxin injected (Fig. 2).

In our experiments, the concentration of picrotoxin reaching the central and peripheral nervous system are expected to fall within the range which has been shown to specifically block GABA-mediated peripheral inhibition ( $5 \times 10^{-6}$  M to  $4 \times 10^{-5}$ M) (ref. 13). Other physiological effects which have been reported<sup>17</sup> in the  $5 \times 10^{-5}$  M to  $10^{-2}$  M range are unlikely to account for the behaviour we observed.

Picrotoxin injections caused as many as 8 deaths in a group of 20 treated flies. Flies which survived recovered their normal behaviour on the day following treatment.

The motor elements of the paralysed fly seem to be functional but the possibility that paralysis may be caused by the reduced excitability of certain motor elements cannot be ruled out. In these circumstances, normal levels of inhibition may cause paralysis, while the blocking of normal inhibition may have caused the movements that we observed. On the other hand, augmented inhibition still provides a reasonable explanation for a paralysis which can be overridden or disinhibited.

# Origin of Nicotiana tabacum L. detected by polypeptide composition of Fraction I protein

THERE is no well-authenticated record of the occurrence of Nicotiana tabacum, the commercial tobacco plant, in the wild state, and so its origin and evolution are of great interest. N. tabacum (n=24) is believed to have arisen by chromosome doubling after hybridisation of N. sylvestris Spegazzini and Comes (n=12) with a species in the Tomentosae section of Nicotiana. Goodspeed and Clausen¹ suggested that N. tomentosa Ruiz and Pavon (n=12) was the species, but Clausen<sup>2</sup> amended it to N. tomentosiformis Goodspeed (n=12). Goodspeed<sup>3</sup> favoured N. otophora Grisebach (n=12), however, because of its present-day geographical distribution; N. otophora is found together with N. sylvestris in an area on the eastern slopes of the Andes whereas N. tomentosiformis occurs further north where N. sylvestris has not been found. Later evidence, however, suggests N. tomentosiformis as the more likely progenitor of N. tabacum. Gerstel<sup>4</sup>, from an analysis of the segregation of artificial polyploids of N. tabacum × N. tomentosiformis and N. tabacum $\times$  N. otophora, concluded that N. tomentosiformis showed the greater chromosome homology with N. tabacum, and Sheen<sup>5-7</sup> from an analysis of isoenzyme patterns and sterol composition supported the conclusion that N. sylvestris and N. tomentosiformis were the likely progenitors of N. tabacum. From an analysis by isoelectric focusing of the polypeptide composition of Fraction I protein isolated from N. tabacum and the putative progenitor species, we now report that N. tabacum arose from the hybridisation of N. sylvestris  $\mathcal{P} \times$ N. tomentosiformis 3.

Fraction I protein (ribulose 1,5-diphosphate carboxylase) consists of two kinds of subunits which differ in size. The large subunits are coded by chloroplast DNA8 whereas the small subunits are coded by nuclear DNA9. By isoelectric focusing in 8 M urea the large subunit is resolved into three polypeptides and the small subunit into one or more polypeptides<sup>10</sup>. The patterns obtained are characteristic of each species of Nicotiana; no variation of pattern has been observed within any species although many plants from several seed collections have been examined. The polypeptide patterns for Fraction I

Fig. 1 Polypeptide composition of Fraction I proteins from N. tabacum and the putative progenitor species. Crystalline Fraction I protein was dissolved in 8 M urea-0.5 M Tris-HCl, pH 8.5 and reduced by the addition of dithiothreitol. The protein was S-carboxymethylated by the addition of iodoacetic acid, and after 15 min excess iodoacetic acid was removed by passage through a 1×7 cm column of Sephadex G-25 (coarse). Protein (20 µg per sample) was then applied to a prefocused 4.5% polyacrylamide gel slab containing 1% Ampholine, pH 5-7, and 8 M urea. Isoelectric focusing was performed for 18 h at 300V. Polypeptide bands were stained with bromophenol blue. Minor bands marked by arrows are artefacts arising by carbamylation of the protein by cyanate present in urea solutions<sup>10</sup>. Samples, from left to right, were N. otophora, N. tomentosiformis, N. tabacum and N. sylvestris. Large subunit polypeptides, pH 6.5; small subunit polypeptides, pH 6.0.

Fig. 2 Polypeptide composition of Fraction I proteins. Fraction I proteins were S-carboxymethylated and subjected to isoelectric focusing as described for Fig. 1. Arrows indicate artefacts due to carbamylation of the protein. Band splitting is due to the reaction of polyphenols with the protein during isolation (J.C.G., S.D.K. and S.G.W., unpublished results). All samples were 20  $\mu$ g protein. Samples, from left to right, were N. sylvestris  $\times$  N. otophora (n=24), N. sylvestris, N. tabacum, N. sylvestris  $\times$  N. tomentosiformis (n=24).

protein isolated from seven different cultivars and a polyploid series of N. tabacum were all similar (K. Chen, S.D.K., J.C.G. and S.G.W., unpublished results). Isoelectric focusing of Fraction I protein therefore readily provides phenotypic markers for both the nuclear and chloroplast genomes11.

Crystalline Fraction I protein was prepared from young leaves by a simple method<sup>12</sup>. Modification of the homogenisation buffer was necessary to obtain crystals from N. tomentosiformis and N. otophora; Dowex 1-( $\times$ 2) (20% w/v), KCN (1 mM), sodium metabisulphite (10 mM) and bovine serum albumin (0.1% w/v) were included in the homogenisation buffer to prevent interaction of the protein with polyphenols18. The Fraction I proteins were recrystallised three times before analysis of the polypeptide compositions by isoelectric focusing.

The polypeptide compositions of Fraction I proteins isolated from N. tabacum and its putative progenitor species are shown in Fig. 1. The protein from N. tabacum is composed of three polypeptides in the large subunit and two polypeptides in the small subunit. Comparison with the polypeptide compositions of Fraction I protein from the other three species indicates that N. sylvestris contributed the large subunit polypeptides and therefore was the maternal parent in the original hybridisation. N. sylvestris also contributed one of the two small subunit polypeptides of N. tabacum, the other polypeptide being contributed by N. tomentosiformis. This analysis indicates that the original hybridisation was N. sylvestris  $9 \times N$ . tomentosiformis 3 and that N. otophora was not involved in the origin of N. tabacum.

To further verify this conclusion Fraction I proteins were isolated from experimentally-produced hybrid plants and the polypeptide compositions were analysed by isoelectric focusing. As shown in Fig. 2, the polypeptide composition of Fraction I protein isolated from the amphidiploid (n=24) of N. sylvestris  $\times N$ . tomentosiformis is exactly the same as the composition of the protein from N. tabacum, whereas the Fraction I protein from the amphidiploid (n=24) of N. sylvestris  $\times$  N. otophora has a different small subunit composition from the protein from N. tabacum. The amphidiploid of N. sylvestris  $\times N$ . tomentosiformis is taxonomically indistinguishable from N. tabacum and is readily crossed with tobacco cultivars.

The analysis of Fraction I proteins therefore provides a convenient means for determining the origin of plant species that have arisen by interspecific hybridisation. The particular advantage in the use of Fraction I protein is that, because the large subunit polypeptides are inherited solely from the maternal parent, it is possible to determine the exact parenta, in the original hybridisation.

The multiple polypeptide compositions of the large at small subunits of Fraction I proteins have also been demostrated in the proteins isolated by conventional chromatograph methods from spinach (Spinacia oleracea), soybean (Glyci. max) and barley (Hordeum vulgare) (K. Chen, S.D.K., J.C.( and S.G.W., unpublished results). It therefore seems probab that the method used with the Nicotiana species can be applie to studies of the origin of species in other plant families.

# Lithium treatment reduces morphine self-administration in addict rats

RECENT reports suggest that opiate-seeking behaviour i. experimentally-addicted animals can be reduced by administer ing other drugs, such as α-methyl-p-tyrosine and haloperidol1-4 and that haloperidol can also alleviate symptoms of heroir withdrawal in man<sup>5</sup>. Both drugs have been shown to reduc morphine-induced hyperactivity in mice6.

Lithium also has been shown to interact with morphine: ; can sometimes reduce morphine-induced hyperactivity is mice7,8 and potentiate morphine analgesia in rats9. We have therefore investigated the possibility that lithium may affec the amount of voluntary ingestion of morphine by addict rats

Naive rats normally reject solutions of morphine, presumabl because of their bitter taste, but with a suitable drinkin schedule they eventually learn to consume appreciable amounts<sup>10,11</sup>, especially if the morphine is given in solution of sucrose12.

Male hooded rats, weighing 180-200 g at the beginning of the experiment and singly housed, were first trained to satisfy their daily fluid requirements during a limited time (1200h-1500h

with food being available *ad libitum*. We have shown that rats readily adapt to this schedule and maintain apparent good health for at least 12 months<sup>13</sup>.

The rats were then made dependent on morphine by being given bottles containing solutions of 10% w/v sucrose +0.5mg ml<sup>-1</sup> morphine hydrochloride (SM) as their only source of fluid. Within a few days they learned to drink more of this solution than they had previously drunk of water. To test the strength of their preference for SM the animals were, after 6 weeks of this forced SM drinking, given daily choices between two bottles which contained either SM or a solution of 10% sucrose alone (S). On average the rats drank some 57% of their total fluid intake in the form of SM. There were considerable differences among them but individual rats were remarkably consistent over long periods of time. (Three out of the seventeen rats were excluded from the experiment as they persistently rejected the SM; nevertheless the statistical comparisons reported here remained significant even with the three rats included in the analyses.)

Fluid consumption was measured throughout by weighing the drinking bottles and applying a correction for spillage in the course of placing and removing bottles from the cages. The positions of the bottles (right or left) were varied randomly each day to allow for possible positional preferences. Statistical comparisons are based on two-tailed *t* tests and on analyses of variance designed to take into account repeated measures on the same subjects<sup>14</sup>.

After 3 weeks of daily SM/S choices, the rats were prepared for lithium administration by being weighed and injected intraperitoneally with 13 ml kg<sup>-1</sup> of isotonic saline 3 h before the beginning of their daily drinking period for 2 weeks. Then half the rats were injected intraperitoneally with 2 mmol kg<sup>-1</sup> of an isotonic LiCl solution and half continued being injected with saline. The particular dose of LiCl was chosen because our previous experiments had shown it to be behaviourally effective and without manifest toxic effects<sup>15</sup>, whilst yielding plasma levels approximating the lower end of the therapeutic range in man<sup>16</sup>. As lithium efflux from the brain is rather slow it is likely that our schedule of injections was adequate for maintaining fairly constant brain Li levels<sup>17</sup>.

After the very first injection of LiCl, the rats reduced their normal intake of SM from 23 ml d<sup>-1</sup> to 15 ml d<sup>-1</sup>, that is, by approximately 35%, and increased the intake of S by 47% from 15 to 22 ml d<sup>-1</sup> (P < 0.05). This pattern of drinking

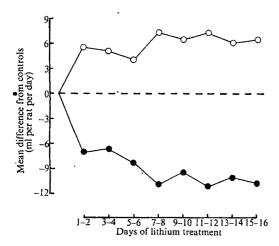

Fig. 1 Addicted rats which were given daily choices between solutions of,  $\bullet$ , 10% sucrose + 0.5 mg ml<sup>-1</sup> morphine hydrochloride (sucrose-morphine) and,  $\bigcirc$ , 10% sucrose alone (sucrose), were injected daily with either 13 ml kg<sup>-1</sup> of isotonic saline or with 2 mmol kg<sup>-1</sup> of LiCl (n=7 per group). Lithiumtreated rats reduced their consumption of sucrose-morphine from 23 ml d<sup>-1</sup> to an average of 15 ml d<sup>-1</sup>, saline controls (---) increased theirs slightly. The results are represented as mean differences from controls.

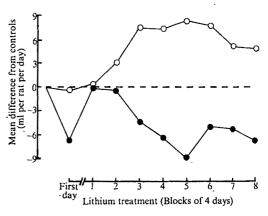

Fig. 2 Addicted rats which were given daily choices between sucrose-morphine ( $\bullet$ ) (Fig. 1) and tap water ( $\bigcirc$ ) were injected with 2 mmol kg<sup>-1</sup> of isotonic LiCl (n=9) or 13 ml kg<sup>-1</sup> of saline (n=8). Lithium treated rats reduced their sucrose-morphine consumption consistently only after some 12 days. The results are presented as differences between LiCl and saline controls (---).

•persisted relatively unchanged throughout the 16 d of lithium treatment (Fig. 1). Lithium-treated rats consistently drank less SM ( $F = 10.5 \, d.f. = 1$  and 12, P < 0.01) and more S (F = 5.5, P < 0.05).

The possibility could not be excluded that these changes in the relative amounts of the two fluids consumed might have been the result merely of an interaction of lithium with taste, that is, lithium (injected intraperitoneally) could have increased the bitterness (and thus the aversiveness) of the SM, or it could have increased the relative palatibility of the S. Therefore, in a second experiment, 24 rats, after being accustomed to satisfying their thirst during the 3 h periods each day, were divided randomly into two groups. Twelve rats were given solutions of 10% sucrose+0.025% quinine hydrochloride<sup>11</sup> (SQ) and twelve 10% sucrose solution alone as their sole source of fluid for 5 weeks. This concentration of quinine proved, initially, to be as aversive as the SM at the beginning of the previous experiment. When the SQ rats were subsequently given daily choices between SQ and S, they persistently drank some 40% of their daily fluid intake in the form of SQ. The remaining twelve rats which had been given sucrose alone to drink continued to receive S only. All rats were then handled and injected with saline for 2 weeks, and as in the previous experiment, they were divided into equal groups which continued to be injected with saline or were given 2 mmol kg<sup>-1</sup> isotonic LiCl for 2 d. Lithium treatment had no effect on the amounts of either SQ or S consumed, regardless of whether the rats had a choice between SQ and S, or were given S alone.

These results suggest, therefore, that the reductions in the amount of morphine ingested during lithium in the SM experiment were unlikely to have resulted merely from changes in the palatibility of the fluids, as in the SQ experiment lithium did not alter the consumption of either S or SQ.

To analyse the lithium-morphine interactions further, an experiment was devised in which the rats would voluntarily consume much greater amounts of morphine (44 mg kg<sup>-1</sup> d<sup>-1</sup>) than in the original experiment (27 mg kg<sup>-1</sup>, P < 0.001). This was achieved by training 17 rats to drink SM in a way similar to that used in the first experiment, but in this instance the rats were given a choice between SM and plain tap water. They consequently drank more than 90% of their total fluid requirements in the form of SM. When, at the appropriate stage of the experiment, they were injected with 2 mmol kg-1 LiCl their SM consumption was reduced (F = 29.7, d.f. 1 and 15, P <0.01) and their consumption of water increased (F = 29.7,P < 0.001); however, in these rats the reduction of morphine intake became consistent only after some 12 d (Fig. 2), possibly because the degree of their dependence was based on a much higher dose of morphine.

It seems fair to conclude that we have clearly demonstrated a robust interaction between morphine and lithium substantial reductions of morphine self-administration were obtained in two different experiments. Should further research establish the generality of these results, their possible implications for clinical practice seem obvious.

We thank David Blundell for help with the experiments, Elizabeth Paul for help with statistics, Dr D. H. Jenkinson and Professors J. W. Black, A. Graham and H. O. Schild for comments and the Medical Research Council and the Foundations Fund for Research in Psychiatry for support.

# **Experience modifies morphine-induced** behavioural excitation of mice

In many animal species, relatively low doses of morphine produce not only analgesia but also a state of behavioural excitation, restlessness and increased locomotor activity which has been defined as 'running fit'1. A large intraspecific variability in locomotor activity has been recorded after the same dose of opiates2 and clear strain differences have also been reported. Morphine for example, has been shown to enhance the locomotor activity of C57BL/6J mice and to drastically reduce it in the DBA/2J strain3.

In man a number of studies indicate that the mechanisms responsible for individual differences in the reactivity to different psychotropic agents such as tranquillisers or hallucinogens are under genetic control<sup>4,5</sup>. A number of environmental, social and psychological factors, however, may also play a role in the determination of the effects of many psychotropic agents such as psychedelic drugs or opiates6 and it is generally acknowledged that the social environment influences the action of centrally acting drugs, These factors have been scarcely studied in animals but a number of experiments demonstrate that drug action is affected by group interactions or by the environment. In particular, Steinberg and her associates, investigating maze exploratory behaviour in individual rats, have shown that

past experience can have a very marked effect on, or even abolish the increase in, activity which normally results from different drugs or drug mixtures.

Our studies were designed to see if the stimulating effects of morphine on behaviour are determined, in addition to genetic mechanisms, also by environmental factors. C57BL/6J mice were used in this experiment as this strain was shown to be particularly reactive to the stimulating effects of morphine on locomotor activity as measured by a procedure previously described10. We first tested the effects of a single morphine injection on the motor activity of eight naive mice during a 25 min session. Morphine-HCl was injected intraperitoneally at a dose of 20 mg kg<sup>-1</sup> which was found to exert a clear effect on motor behaviour in this strain<sup>3</sup>. A threefold average increase was evident in the morphine-injected group as related to the activity evident in eight other naive mice injected with saline (Table 1; t=16.8, P<0.001). To test the effects of past experience on the action of morphine another group of rhice was placed for 25 min in the toggle-floor boxes and immediately after the end of this session the mice were

Table 1 Effects of morphine on the locomotor activity of naive and experienced mice

Treatment	and activity c	ounts ±s.e.	during	1st and 2nd	i sessions
Group	1st se	ssion		2nd se	ssion
1	Saline	$59.1 \pm 3.6$			-
2	Morphine	$161.4 \pm 9.1$			-
3		$51.8 \pm 3.0$		Saline	$41.5 \pm 2.9$
4	Saline	$56.5\pm4.0$		Morphine	$45.3 \pm 3.5$
				•	

Each session was 25 min long. Groups 1 to 4 were injected with saline or morphine (20 mg kg<sup>-1</sup>) immediately before the first session. Immediately after the end of the first session groups 3 and 4 were injected again with saline or morphine and tested again. Each group consisted of eight mice.

injected with morphine and tested again for 25 min. The performance during the morphine session was compared with that of a control group subjected to a similar schedule and injected with saline. Table 1 shows that past experience modifies the effects of morphine since no stimulating effect was evident in these conditions in relation to the control group (t=0.36, P>0.05).

Next we designed another schedule of experience in which the animals were placed for 25 min in the togglefloor box in the absence of drug. The mice were subjected to a second 25 min test 6 h later and at the end of this session they were injected with saline or morphine and immediately retested during a third 25 min session. By using this procedure the animals were more 'experienced' than in the previous schedule and the injection of morphine not only did not produce a stimulating effect but also resulted in a complete block of their activity (Fig. 1. groups A and B). Visual observation of the behaviour of the mice did not reveal any type of circling or other stereotyped behaviour.

At the end of this session the animals were removed from the toggle-floor boxes and returned to their home pens in which they were caged in groups of eight. When returned to their home cages the morphine-injected mice became very excited and exhibited immediately a very high leve of locomotor behaviour. After a few minutes of exploration of their home cage they were returned to the toggle-floor boxes where they exhibited extremely high levels of locomotor behaviour during a 25 min session (Fig. 1 groups A and B, session 4). Thus, exploration of a different environment was followed by the 'running fit' in the same 'experienced' animals in which the injection of morphine previously resulted in a block of their activity. Being in a group of eight (instead of being isolated in the togglefloor boxes) might have been another reason that contributed to the arousal of the mice. This result was replicated in two additional experiments.

It was possible to induce the 'running fit' in the experienced animals in which morphine resulted in a block of their locomotor activity by leaving the mice in the togglefloor boxes and switching off the 40 W lamp which was normally illuminating the sound-insulated cabin 1 m above the eight toggle-floor boxes (Fig. 1, group C). Similarly, in another group of animals the action of morphine turned from a blocking to a stimulating effect if a solution with a strong smell of eugenol was sprayed inside the cabin at the end of the morphine session. Thus, experience of the

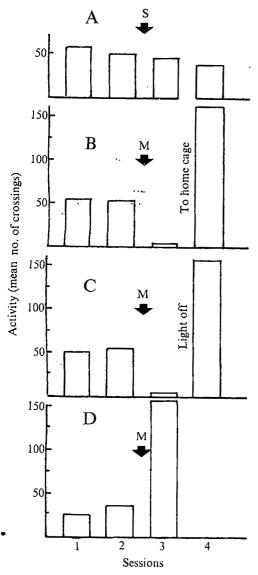

Fig. 1 Effect of past experience on the morphine-induced 'running fit'. Groups A to D were subjected to two 25 min sessions (1 and 2) spaced 6 h apart. Animals of group D were subjected to cortical spreading depression during these two sessions. Immediately after session 2 the mice were injected with saline (S) or morphine (M) (20 mg kg<sup>-1</sup>) and tested again for 25 min (session 3). At the end of this session the mice were either returned to their home cage for 2-3 min and then tested again for 25 min (session 4) or they were subjected to an additional session in fotal darkness. The performance of groups A and B during the third and fourth sessions was significantly different (t=13.1, P < 0.001; t=17.0, P < 0.001). Similarly, the performance of group C during session 4 was different from that of a control group (not shown) injected with solitons and the statements. (not shown) injected with saline and subjected to a similar schedule (t=14.9, P<0.001). In the mice tested under spreading depression during sessions 1 and 2 morphine significantly enhanced the performance in relation to that of another group of animals injected with saline (t=17.9, P < 0.001).

environment results in a suppression of the morphineinduced running fit or even in a complete block of the animal's activity while a change of the environmental conditions (such as returning the mice to their home cage, a change from light to darkness, or an olfactory stimulus) is followed by the appearence of the 'running fit' effect.

To show that experience of the environment results in a clear change of the behavioural effects of morphine we subjected a group of mice to functional decortication11 while they were subjected to two 25 min sessions in the toggle-floor boxes. In these mice the injection of morphine after the second session resulted in a clear excitatory effect (Fig. 1, group D). Also this finding shows the importance that sensory inputs and experience exert in modulating the effects of the opiate.

While further experiments are necessary to assess why the effects of morphine not only are abolished but result in a suppression of exploratory behaviour in the experienced mice, our findings indicate the importance of the environment in influencing the action of centrally acting drugs<sup>12</sup>. Study of these factors in animals might provide a useful tool for analysing the type of effects of morphine and of a number of 'social drugs' in man depending on his social environment.

# Cervical somato-sensory evoked responses in man

It has been known for over 20 yr that cerebral responses evoked by peripheral nerve stimulation can be recorded from the scalp in man and that they may be altered by disease. But clinical application has been impeded by the variability of the cortical response, particularly of its later components, and by lack of knowledge of its origins. We have explored the possibility of recording from lower levels of the central sensory pathway.

Here we report a response which can be recorded over the back of the neck and base of the skull, which appears to be of nervous origin and has stable properties. It is likely to be useful in the study of neurological disease, notably in conditions such as multiple sclerosis where central conduction may be interrupted or delayed.

Somato-sensory evoked responses (SER) have been recorded

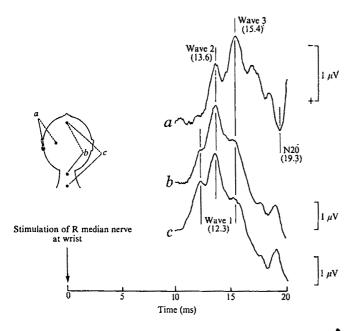

Fig. 1 Cervical somato-sensory responses evoked from a normal 20 yr old female and averaged from 256 stimuli. Electrode placement for ear lobe-parietal region (a) selectively emphasises wave 3. b and c are responses recorded from electrode sites used routinely (C2 and C7).

from surface electrodes over the cervical spinal cord in 30 normal subjects. The stimulus was a square-wave pulse of 0.3 ms duration applied to the median nerve at the wrist. Conventional surface recording and signal averaging techniques were used. Silver disk electrodes were placed between the sixth and seventh cervical spines (C7) and immediately rostral to the second cervical spine (C2) with a common mid-frontal reference electrode (Fz, 10–20 system). The cortical response from the hand area of the contralateral parietal region was simultaneously recorded. The amplifiers had a flat frequency response from 2 to 1,000 Hz. The overall response of the system was 3 dB down at 1,500 Hz, rolling off at 24 dB octave<sup>-1</sup> thereafter. The averager sampling rate was 10 points ms<sup>-1</sup> and 256 responses were summed.

Preliminary experiments showed that with increasing stimulus strength there was an initial steep rise in amplitude of response and a moderate reduction in latency, both measurements levelling off at stimulus currents approximately three times sensory threshold. A stimulus of approximately four times sensory threshold was therefore used in routine recordings. This produced a tolerable muscle twitch and was not painful. The responses from finger stimulation did not differ from those evoked from the wrist apart from the expected increase in latency and reduction in amplitude. Variation in stimulus rate between 1–10 s<sup>-1</sup> produced only minor alterations in the shape of the cervical response, in contrast to the marked changes observed in the cortical response.

With standardised stimulation at a rate of 1 s<sup>-1</sup> a predominantly negative wave of complex shape was recorded from all subjects (Fig. 1b and c). The mean amplitude (onset to peak) was 3.0 µV (range 1.4-4.9). The onset latency ranged from 9.4-11.8 ms and peak latency from 11.9-14.3 ms, both measurements being strongly correlated with arm length (Fig. 2). The mean duration was 7.0 ms (range 5.7-8.3). The cervical response was almost completed before the onset of the first component of the cortical SER at about 16 ms. Although there was some variation between individuals, three distinct peaks could be recognised within the cervical SER in all subjects. The major peak (wave 2) was preceded by about 1.3 ms by a minor peak (wave 1) and followed by a further minor peak (wave 3) after a similar interval.

This response is unlikely to be of muscular origin. In relaxed subjects its latency, amplitude and shape were remarkably constant when recorded on different occasions and changes in latency and amplitude with changing stimulus intensity closely paralleled those of the first major component of the cortical SER (N20-P28), which is accepted as neurogenic. Activity in the neck muscles due to anxiety or voluntary contraction obliterated the response whereas a myogenic response would have been enhanced. Goff, et al. recently recorded, but did not characterise, a wave of similar latency (N14) over the cervical spine evoked by stimulation at the wrist and presented convincing evidence that it was neurogenic.

Cracco<sup>2</sup> recorded from surface electrodes at various sites over the spinal cord following peripheral nerve stimulation and concluded from changes in the onset latency that the evoked response was a travelling wave. We found no such increase in latency between the lower and upper neck. The peak latencies of all three components were identical when recorded from caudal and rostral sites over the cervical spinal cord and there was no consistent change in the less sharply defined onset latency. The relative amplitudes of the three components showed systematic variation with recording site, that of wave 1 being always greatest at C7, falling off both rostrally and caudally. The amplitude of the main peak (wave 2) was similar when recorded at C7 and C2. Wave 3 could be emphasised selectively by recording from mastoid or earlobe. Some of these variations are illustrated in Fig. 1. The findings with regard to both latency and amplitude are more consistent with generation of the components of the cervical response from fixed sites than with a travelling wave in the dorsal column system. The possible locations of these sites, which may include dorsal root ganglia, spinal cord interneurones, dorsal column nuclei and cerebellum, have not yet been elucidated. There appears to have been no relevant comparison of surface with direct recordings in the experimental animal.

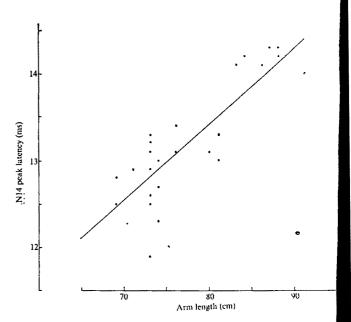

Fig. 2 Relationship between peak latency of cervical response evoked by median nerve stimulation at wrist and arm length measured from wrist to seventh cervical spine (correlation coefficient 0.85).

Surface recordings, in contrast to recordings from the epidural space<sup>3</sup>, are readily repeatable in normal subjects and patients with neurological disease. Work is now in progres designed to clarify the sites of origin of the components of the cervical SER and their use in the study of disease of the central nervous system.

This work was supported in part by the Multiple Sclerosis Society of Great Britain.

# Luteinising hormone and testosterone in man

In mammals, including man, specific sexual stimuli can affect the secretion of luteinising hormone (LH) from the pituitary and testosterone from the testis. For example, the presence of the female and copulation is associated with an increase in the blood levels of testosterone in rabbit', rat', bull<sup>3</sup> and man<sup>4</sup>, and in each species excluding man this has been shown to be related to an elevation of blood plasma LH<sup>1,3,5</sup>. Among animals, merely the presence of a receptive female may induce these changes in the absence of intercourse2,3,8 indicating that in some species visual and olfactory cues alone are sufficient to elicit an endocrine response. In man the anticipation of female company after long periods of abstinence apparently has similar effects<sup>6</sup>. Very few studies of this sort have looked at both LH and testosterone secretion simultaneously in sufficient detail to provide convincing evidence of short term endocrine changes related to behaviour. The aim of my study was to establish whether the normal pulsatile secretion of LH and testosterone in men could be altered by a specific sexual stimulus. It was decided to expose male volunteers to a film sequence which included scenes of human behaviour which were judged to be sexually provocative.

Eight healthy men aged between 24 and 29 yr were recruited. Blood samples were collected at intervals of 10-40 min using an indwelling needle inserted into a forearm vein. The trials lasted 6-7 h starting at about 1700h and only two or three subjects were studied in any one evening.

After a meal each subject spent the evening relaxing, reading and talking. The film projector was placed in a separate room and each person could view the film in complete isolation, and was free to study and relate to the scenes as he wished. None of the volunteers knew at what time they would be called to the room; they were informed at the beginning of the trial that the film may or may not contain scenes of sexual interest, and later they each completed a questionnaire indicating their reactions during the evening.

Seven out of eight subjects recorded the film sequences as sexually stimulating to a greater or lesser degree, and experienced full or partial erection of the penis at this time. The feeling of sexual excitement persisted in these subjects ■t the end of the viewing period.

There were no changes in blood levels of LH or testoterone in the subjects which could be definitely related to he films (Fig. 1). Plasma LH concentrations changed -narkedly during each trial period; intermittent high values were followed in many cases by progressively decreasing alues producing a pattern indicative of the documented sulsatile release of gonadotrophins from the pituitary<sup>7,8</sup>. Whese discharges occurred at irregular intervals; two out of ight subjects produced an LH surge during the viewing seriod which had a frequency not greater than expected in n unstimulated situation (LH surge in a resting situation

every 2-4 h would produce one or two releases in any 30 min period in eight subjects). One noticeable feature was that LH values were generally high in all subjects at the beginning of the trial, which seemed to be related to the experience of the initial vein puncture.

Testosterone concentrations fluctuated during the evening in a normal pattern<sup>8-10</sup> unrelated to the film period. By relating the testosterone values to the main LH peak for each individual and calculating a mean steroid level for the eight studies, it was possible to demonstrate a temporal relationship between LH and testosterone concentrations in the serial samples (Fig. 2). An endogenous surge in LH was associated with a progressive rise in testosterone levels which were at a maximum (+26% of value at LH surge) at 90 min after the increased LH stimulus. There was considerable variation, however, in the timing and extent of the testis response in the different cases.

I conclude that normal male subjects can experience varying degrees of sexual excitement without any concomitant change in blood LH and testosterone levels. Very few studies on man have revealed short term endocrine changes related to behaviour. Fox et al.4, studying a single individual claimed to have found significantly elevated •plasma testosterone levels during and within 5 min of coitus, and similar findings are indicated by Steinbeck<sup>11</sup>. Yet there is no evidence that these steroid changes are induced by elevated gonadotrophin levels<sup>4,12</sup>. Indeed, the present study illustrates that the human testis is relatively, sluggish in its response to endogenous changes in LH, and it can be assumed that any sexual stimulus affecting LH would not

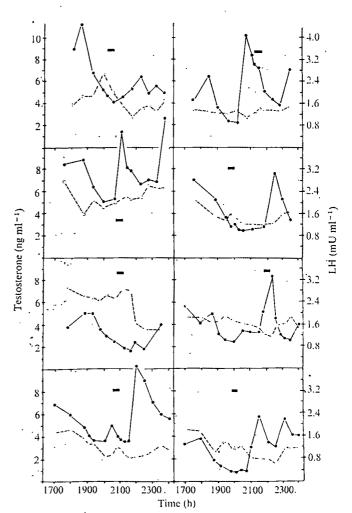

Fig. 1 Blood plasma levels of LH (•) and testosterone (()) measured by radioimmunoassay<sup>10,18</sup> in eight normal men for a 7 h evening period during which they viewed a short sexually stimulating film. ——, Film.

# Curren Titles in Bacteriolog

Vol. 1—January to December 1975

specifically interest him, and yet reassures him at the same time by efficient classification and crossreferencing that he has seen references to all relevant literature contemporaneously published.

**NEW FOR 197** 

A low-cost comprehensive monthly current awareness service for bacteriologists world-wide

This new service will provide to individual bacteriologists a comprehensive listing of titles in English of papers published throughout the world in over 4,300 primary journals, books, monographs, reviews and symposium proceedings. Entries will be classified in each issue under the headings indicated below, and will contain sufficient information to facilitate the acquisition of reprints. The subject classification of entries in each issue offers the busy scientist the opportunity to scan only those sections of a total field which

Main subject classifications (sub-divisions not shown):

Identification & taxonomy Mycoplasmatales Rickettsiales Cytology **Biochemistry Growth & nutrition** Methodology, media & cultures Genetics Phage-host interactions

Plasmids & antibiotic resistance Effects of physical & chemical factors Diseases of man Diseases of animals Diseases of plants Experimentally-induced diseases Epidemiology & epizootiology

Immunology Toxins Gnotobiotics **Ecology & distribution** Miscellaneous topics **Book notices** Notification of proceedings

Subscription rate:

£12.00/US\$30.00 by air throughout the world . Please fill in the coupon below to reserve your free copy of the first issue. If you are prepared to place a firm order on this coupon immediately you will be invoiced at a special 10% discount.

Please see overleaf for full range of IRL publications

# Abstracts journals for current a

abstracts are lassified in each ssue into subject ections coinciding with the main areas fresearch. Icientists therefore an immediately ocate those sections hat interest them and be informed of ll work recently sublished in their pecific areas.

ach IRL abstract is idexed, often by as nany as 12 entries.

uring 1975 IRL

\*\*cpects to publish

\*\*ver 130,000

\*\*ostracts selected

\*\*om the regular

\*\*canning of over

300 primary

\*\*terature sources.

Il abstracts are in Inglish, translated om any language.

ostracts are formative and clude the present dress of athors for print requests.

Labstracts are blished within -20 weeks from e appearance of e primary paper U.K.

# Nucleic Acids Research

Monthly-Volume 2 January-December 1975

he contents of recent issues of this ew journal are shown alongside.

apers submitted by the 18th fthe month, if accepted, will appear the following month's issue. The urnal includes only full papers in aglish describing research on hysical, chemical, biochemical or ological aspects of nucleic acids. poweritten manuscripts are produced photographically thus iminating the need to correct proofs a dresulting also in fast publication. apers are refereed as quickly as assible.

all instructions for Authors are vailable from the editorial offices from below.

#### ditorial offices

rofessor A. S. Jones and r. R. T. Walker, epartment of Chemistry, niversity of Birmingham, O. Box 363, Birmingham B15 2TT. ngland.

ofessor Dieter Söll, ile University, ox 1937 Yale Station, ew Haven, Connecticut 06520, S.A.

ucleic Acids Research is included Current Contents.

## abscription rate

2.50/US \$95.00 for 1975 lendar year volume.

#### Contents

Volume 1 number 8 August 1974 Heterologous mischarging as a means of tRNA fractionation. I. Behaviour of E.coli phenylalanyl-tRNA val on BD-cellulose. E. Rosenmann and M. Krauskopf: Urea perturbation and the reversibility of nucleohistone conformation. C.Chang and H.J.Li: The thermal denaturation of DNA: average length and composition of denatured areas. A. P. Russell and D. S. Holleman: The preparation and characterisation of chromatin from third instar larvae of Drosophila melanogaster, P. W. Andrews and D. B. Roberts: Proton magnetic resonance studies of ultraviolet-irradiated apurinic acid. R. O. Rahn and T. Schleich: The fractionation of t-RNA on N,N'-bis (3-aminopropyl)-piperazine substituted-Sepharose, R. Leberman, R. Giovanelli and Z. Acosta: CD studies on the conformation of some deoxyoligonucleotides containing adenine and thymine residues. Ch. Zimmer, E. Birch-Hirschfeld, R. Weiss: Oligonucleotide conformations. 4. Temperature and solvent effects on different uridylyl-uridines. A. André, W. Guschlbauer, and A. Holý: The premelting of nucleoprotein: role of non-histone proteins. F. X. Wilhelm, G. M. de Murcia and M. P. Daune: Deoxynucleotide substitution: a new technique for sequence analysis of RNA. A. Van de Boorde, R. Rogiers, J. Van Herreweghe, H. Van Heuverswyn, G. Volckaert and W. Fiers: Different deoxyribonucleases in human lymphocytes. E. J. Zöllner, W. Helm, R. K. Zahn, J. Beck and M. Reitz: Terminal oxidationreduction of N-acetylphenylalanyl-tRNA blocks initiation complex formation with Escherichia coli 30S ribosomal subunits. J. Ofengand and Z. Hussain.

Volume 1 number 9 September 1974 Mitochondrial DNA polymerase, deoxyribonuclease and ribonuclease H activities from brain of chick embryo. L. Soriano, J. Smith, Y. Croisille and B. Dastugue: Analysis of eucaryotic DNAs with a restriction endonuclease from H. influenzae: isolation of 'hidden' satellite DNAs. G. Roizès: Sequence analysis of nonradioactive RNA fragments by periodatephosphatase digestion and chemical tritium labeling: characterization of large oligonucleotides and oligonucleotides containing modified nucleosides. K. Randerath, E. Randerath, L. S. Y. Chia, R. C. Gupta and M. Sivarajan: The fractionation of calf thymus DNA on histone KAP – Sepharose 4B columns. H. Panusz, J. Bartkowiak, A. Krzywiec, M. Joustra, and A. Płucienniczak: Replication of colicinogenic factor E1 DNA: evidence for a discontinuous replication mechanism. W. L. Staudenbauer Enzymatic methylations: III. Cadaverine-induced conformational changes of E. coli tRNA<sup>fMet</sup> as evidenced by the availability of a specific adenosine and a specific cytidine residue for methylation. D. Wildenauer, H. J. Gross and D. Riesner: Evidence for two waves of induction of DNA enzymes in stimulated human lymphocytes. G. C. F. Pedrali Noy, L. Dalpra', A. M. Pedrini, G. Ciarrocchi, E. Giulotto, F. Nuzzo and A. Falaschi: Isolation and analysis of (Gp), Xp sequences of rat liver 5S RNA by means of restricted ribonuclease T2 hydrolysis. R. Willems, T. Avdonina, A. Lind and L. L. Kisselev.

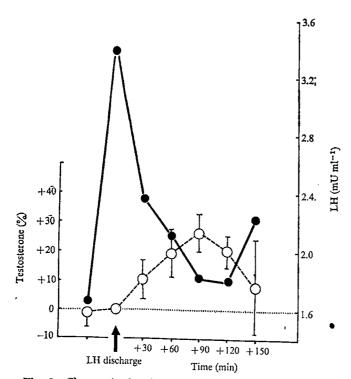

Fig. 2 Changes in the plasma concentration of testosterone in the eight subjects (mean ± s.e.) related to the principle LH peak for the individual studies. A temporal relationship between LH (•) and testosterone (○) is apparent, with testosterone values increasing after the LH discharge and reaching a maximum 90 min later.

show itself in terms of changes in plasma testosterone for some 30-90 min. It seems probable that the observations of Fox and Steinbeck may be accounted for in terms of increased blood flow through the testis which is likely to be important in causing a transitory increase in testosterone<sup>13</sup>. Neural pathways involving the hypothalamus need not be implicated in this response.

While no report has yet described short term changes in LH secretion in man related to sexual stimuli, there still remains the observation that LH levels in my study were increased at the beginning of each trial period. This involved the very first blood sample in several cases and it seems likely that the experience of having the blood sampling needle fitted into the arm may have caused this response; the LH surge occurred at the time of the venapuncture or during the hour afterwards. Studies on 'stress' associated with surgery<sup>1</sup> and army training<sup>15</sup>, as well as foot shock in rats16 and fighting in monkeys17 lead one to expect decreased LH secretion under these conditions. The observation remains, however, as a cautionary note to those using venapuncture to study gonadotrophin levels and it seems possible that a single skin puncture has a greater impact on the hypothalamic/pituitary axis than a 30 min sexually stimulating film.

# Muscular dystrophy and muscle cell death in normal foetal development

ALTHOUGH the application of modern biochemical, morpho logical and experimental techniques to the study of musc disease has greatly extended our knowledge of myopathi processes, the cause of muscular dystrophy continues to elud investigators. McComas et al.1 have suggested that the mote neurones rather than the skeletal muscle fibres are primari affected but this has been seriously questioned<sup>2,3</sup>. My own hypo thesis is based on the concept of embryonic cell death ar stems from observations that I, as well as others, have made on the death of muscle cells in normal human foetuses<sup>4,5</sup>.

Cell death in embryogenesis takes place in a highly predic able manner and all the evidence points to it being genetical controlled. It is a familiar process in eliminating tissues an organs useful only during embryonic life, in the elimination of phylogenetic vestiges and in modelling processes such the formation of clefts or digits. The death of embryonic ce in a tissue such as muscle, where the elimination of cells appear on the face of it, to have no useful purpose, must neverthele serve a function which is probably crucial to the subseque healthy development and growth of that tissue.

I wish to suggest that the basic defect in muscular dystropt is due to a derangement in the normal process of muscle c death during a critical stage in development—possibly between weeks 10 and 16 of foetal life. From previous observations have made in human foetuses, muscle cell death can be see up to about week 16: this is roughly in agreement with Boyd observations4.5.

The derangement in the cell death process might come abo in one of three ways. First, the cell death 'switch' may simp not be activated at the critical stage in muscle developmen As a result the developing muscle fibres do not go through the proper embryological processes (of which cell death is part) and which are essential for the healthy development the tissue. The imperfectly formed muscle fibres would th die off prematurely. Second, the cell death switch may not activated at the correct time in the lifespan of the individu Instead of occurring between weeks 10 and 16 of foetal 1 it is delayed until later in development, or even into the po natal period. On this basis muscular dystrophy can be look upon as a normal process but one which has occurred too la to perform its role in development. Third, the cell dea mechanism may be triggered off at the correct time but t failure is one where the process cannot be turned offmuscle cell death would continue in a relentless fashion un

irtually all the muscle fibres had died. Here again muscular Aystrophy may be thought of as a normal process but one thich continues beyond the period when it is able to play ny useful role. One way in which this could come about ould be if the target cell (muscle fibre) contained a blocking mechanism which in some way failed to neutralise the effects f the agent responsible for the cell death.

Relatively little is known about the way in which cells die suring embryogenesis but it is known that hormones (for rample oestrogens, androgens or thyroxine) are involved in ertain specific instances. It has been shown that in amphibia lyroxine can break down the gills, tail and larval head muscles, hilst in organ cultures of tails of Xenopus the addition of popropriate concentrations of thyroxine causes regression of et tissues. Other possible mechanisms of cell death include me senescence of cells in which excessive amounts of membranous material accumulate until the point is reached when the etabolism of the cell is impaired. Errors in the metabolism of proteins which build up in the cytoplasm and block further all respiration is another possibility. In the case of embryonic all death the elimination of cells is an extremely rapid one and it is difficult to accept that cell senescence or a build up in monormal proteins could act sufficiently quickly. On the other and a genetic mutation or the production of metabolite which recifically blocks cell respiration could cause very rapid death recells. Such a specific blocking metabolite might act in a mewhat analogous fashion to the injection of certain fluoro impounds into laboratory animals, which causes very rapid apairment of cell function and structure by blocking the cidative metabolism of cells in a highly specific manner<sup>8</sup>. Morphological studies provide no clue as to the mechanism f cell death, but in the regression of tails of Xenopus larvae e death of muscle cells is accompanied by phagocytosis and auch lysosomal enzyme activity9. Although in humans the

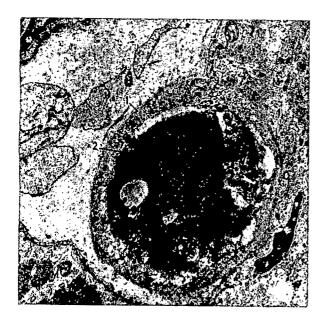

Fig. 1 Foetal muscle at 12 weeks. Quadriceps muscle was obtained from apparently normal human foetuses of either sex fresh from therapeutic abortions. Cubes of tissue (1 mm<sup>3</sup>) were fixed in 3% buffered glutaraldehyde at 4°C (pH 7.3) for th. This was followed by washing in buffered sucrose, postixation in OsO<sub>4</sub>, dehydration and embedding in araldite. Thin sections were stained on copper grids with uranyl acetate and lead citrate. The tissue was examined with an AEI EM6B electron microscope. To eliminate the possibility of traumatic «trtefact in four cases an entire lower limb was fixed immediately n 4% formaldehyde in buffered saline at 4° C and left for 24 h. small pieces of quadriceps were then post-fixed in 2% OsO<sub>4</sub> and processed as before. (1) Phagocytic cell containing ingested cell products (2), with identifiable nuclear remnant (3), M healthy myotubes. (×10,000).

degenerating foetal muscle may be surrounded by mononuclear mesenchymal cells, phagocytosis does not seem to take place on any significant scale<sup>4</sup>. In a recently examined 12-week-old foetus, however, I have observed the apparent ingestion of degenerate cell products in skeletal muscle (Fig. 1).

If, as I am suggesting, the muscular dystrophies are primarily disorders of muscle fibres, why, it may be asked, are some muscle groups severely affected while others are spared, or at any rate affected to a much lesser extent? My hypothesis goes some way to explaining this in that there is evidence to suggest that cell death is extensive in some muscle groups but is less marked or hardly occurs at all in others5.

In my view, to discover insights into the cause of muscular dystrophy, we should look to normal developmental processes in human foetal muscle and in particular the phenomenon of muscle cell death. I have suggested ways in which an upset in this phenomenon might lead to muscular dystrophy, so that these diseases can be looked upon as a normal process but one occurring at the wrong time in the individual's life span or else one which has not been repressed. Further studies of muscle cell death in normal foetuses and the foetuses of mothers who are carriers of the dystrophy gene are needed.

# Liver as major organ of phenol detoxication?

THE ability to detoxicate and eliminate potentially harmful substances from the body represents a defence mechanism, the importance of which is well established. It has been assumed that the protective devices themselves, the detoxication mechanisms, have evolved to protect the organism from potentially harmful chemicals occurring naturally in the environment. These chemicals, usually described as foreign, are rendered harmless by metabolic transformations and modified compounds are subsequently excreted usually in the urine or bile. The liver is generally regarded as the major organ of detoxication.

The work we report here, on the fate of phenol in the rat, necessitates a reappraisal of some hitherto accepted aspects of detoxication. In particular, it focuses attention on the need to re-assess the role of the liver in detoxication.

Whole-body autoradiograms1 were prepared using young rats (approximately 50 g body weight) which had received U<sup>14</sup>C-phenol (10 μCi; 20-40 mCi mmol<sup>-1</sup>) either orally or intraperitoneally. The autoradiograms obtained U<sup>14</sup>C-phenol was administered by either route showed that the level of isotope in areas corresponding to the liver did not, at any time, exceed that of the blood. Thus, the liver has no ability to concentrate either phenol or its metabolites suggesting that U14C-phenol either fails to enter the liver cells or alternatively, that the radioactive molecules have a transient cellular existence due to rapid turnover in the liver. The qualitative

patterns do suggest, however, that the liver is not the principal site of phenol detoxication. Experiments were therefore designed to investigate further the contribution of the liver and determine the sites and extent of extrahepatic detoxication. As phenolic substances are normally presented to the animal through the gastrointestinal tract, initial studies were made to determine the detoxication capacity of the gastrointestinal tract with respect to phenol.

Isolated rat gut preparations were perfused2 with Krebs-Henscheit buffer pH 7.0 containing glucose (500 mg per 100 ml). Segments (30-50 cm) of small intestine were washed free from debris by perfusing with 50 ml of the perfusion medium before attaching to the apparatus. U14C-Phenol was added to the mucosal medium and samples were withdrawn from the circulating serosal and mucosal media over 2 h. Analysis of these samples showed a decrease in the level of radioactivity in the mucosal circulation and a concomitant increase in the level of radioactivity in the serosal circulation. When either  $U^{14}C$ -phenol (10  $\mu Ci$ ) or 10 mg of phenol mixed with U<sup>14</sup>C-phenol (10 μCi) was added to the mucosal medium 50% and 78% respectively of the radioactivity was transferred to the serosal circulation in 2 h. At the end of the experiments the radioactivity in both media was distributed between phenyl sulphate (5%) and phenyl glucuronide (95%). No unchanged U14C-phenol could be detected.

Conjugation of phenol by gut preparations in vitro raises the possibility that the gut is the principal site of detoxication of phenol ingested in the diet and that phenol is transported into the blood after conjugation. This was explored in the whole animal by perfusing the small intestine in situ with media containing U14C-phenol and simultaneously sampling blood directly from the hepatic portal vein.

Wholly anaesthetised rats (phenobarbitone) with bile-duct catheters were prepared and the gut was ligated both at the duodenal-jejunal flexure and at a point about 30 cm distal to the flexure. After washing, to remove intestinal debris, the isolated gut segment was perfused (3 ml min<sup>-1</sup>) in situ with water (30 ml) and the perfusate returned to a mixing reservoir for recirculation. Bile was allowed to join the perfusate circulation at the mixing reservoir.

U <sup>14</sup>C-Phenol (10 μCi) or 10 mg phenol mixed with U 14C-phenol (10 μCi) was added to the circulating perfusate and samples (1 ml) were withdrawn at 30 min intervals over 3 h. Portal blood samples (0.5 ml) were collected through the pancreatico-duodenal vein at 30 min intervals into heparinised tubes and the plasma was removed after centrifuging. In both experiments there was a progressive decrease in the amount of radioactivity in the circulating perfusate. Over the 3 h experimental period the major proportion of the radioactivity was transported from the intestinal lumen and was accompanied by the appearance of radioactivity in portal blood. In all plasma samples, conjugates of U 14C-phenol only were found; U 14C-phenol itself could not be detected. Phenol conjugates appeared in the intestinal perfusate within 30 min but at this time the majority of the radioactivity was still present as unchanged U 14C-phenol. In contrast, after 2 h perfusion, unchanged U 14C-phenol could not be detected and the radioactivity was present as phenyl sulphate (72%) and phenyl glucoronide (28%).

These results strongly support the view that free phenol is not transported as such from the intestinal lumen but in conjugated form. It therefore follows that the role of the liver is minimal in the detoxication of orally ingested phenol. When the gastrointestinal tract is by-passed by intravenous administration of free phenol, however, conjugation with sulphate and glucuronide and subsequent excretion of these conjugates in the urine nevertheless takes place3. In these conditions the liver may assume major importance as a centre of detoxication. This possibility was explored in experiments in which phenol was administered to hepatectomised rats.

Rats were anaesthetised with phenobarbitone and the ureters were cannulated. In test (hepatectomised) rats, hepatic

tissue (60%), the spleen and the gut were removed following appropriate ligations. When U 14C-phenol was administered intravenously to hepatectomised and control rats at dose level of 5 mg kg<sup>-1</sup> and 10 mg kg<sup>-1</sup> body weight the percentage o radioactivity recovered in urine of test and control animals ove 3 h was essentially the same. Furthermore, test and contro urines contained the conjugates of phenol although the glucuronic acid conjugate was proportionally higher in the tes than in control urines. Thus, even in the absence of the live and gastrointestinal tract, formation and urinary secretio of phenol detoxication products still occurs.

Collectively, the results strongly suggest that the detoxicatio aspect of liver function has been over-emphasised for it is show that the liver is not essential to the detoxication of pheno Attention is drawn to the considerable capacity of the gastro intestinal tract to detoxicate phenol. The findings of th investigation point to a major role for the gastrointestina tract in the protection of the whole organism from the potentia toxic effects of phenol. The necessity for such strategically placed detoxication devices is immediately apparent when it recalled that up to 600 mg of phenolic material may be ingeste each day in the normal human diet. The experiments reporte here, demonstrate that, in the case of phenol, this requiremen is satisfied by the intestinal barrier. Other potential detoxicatic sites are thus not presented with exogenous phenol since enters the portal blood in conjugated form only. The important of this latter observation is emphasised by the known effects. phenol on the red blood cells and, in retrospect, it is clear the the transport of phenol in unconjugated form by the bloc represents a highly undesirable and potentially hazardor process with respect to the health of the whole organism.

# Cardiotoxic protein from edible mushrooms

THE cardiotoxic protein volvatoxin has been isolated from edible mushroom, Volvariella volvaceae<sup>1</sup>. We have now isola another cardiotoxic protein from the edible mushroom Flcmulina velutipes (Curt. ex Fries) Sing., which is widely eain the Orient and is canned for local consumption and expo We have called this protein flammutoxin.

Flammulina velutipes fruits throughout the year. Its c initially ovoid and yellow becomes, within one or two da flat and yellowish brown with an edge of lighter colour. I cap reaches a diameter of 2 cm; the stem achieves a length 15 cm and a diameter of 0.5 cm. This mushroom has li taste but a slightly unpleasant smell.

The method of isolation of flammutoxin was similar that of volvatoxin1 except that flammutoxin was obtain between 0 and 60% saturation of ammonium sulphate.

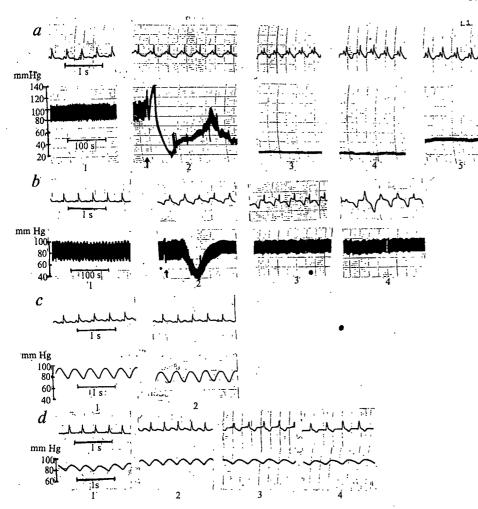

Fig. 1 Effect of a, flammutoxin and b-d, volvatoxin on the electrocardiogram and arterial blood pressure of a 2 kg cat, pentabarbital anaes-thetised (30 mg per kg body weight intraperit-oneally). Upper tracing ECG (lead II); lower tracing, arterial | blood pressure. a, 0.25 mg per kg body weight flammutoxin was injected. 1, 0 time; 2, 1 min; 3, 10 min; 4, 25 min; 5, 60 min; Arrow indicates the time of injection. b, Injection of 1 mg per kg body weight volvatoxin A2; weight volvatokin A2, 1, 0 time; 2, 1 min; 3, 10 min; 4, 60 min. c, Injection of 5 mg per kg body weight volvatoxin A1; 1, 0 time; 2, 60 min. d, Injection of 2 mg per kg body weight the mixed solution of volvatoxin A1 and A2 (weight ratio 1:2). 1, 0 time; 2, 3 min; 3, 5 min; 4, 10 min.

oncentration of flammutoxin in the mushroom was 320 mg g<sup>-1</sup> whereas that of volvatoxin A was 1,100 mg kg<sup>-1</sup>. The xicity of flammutoxin when administered intraperitoneally as determined as described previously<sup>1</sup>. The LD<sub>50</sub> was found be 2.45 mg per kg body weight. The toxicity can be comtetely eliminated by heating a solution of flammutoxin at 100° C or 20 min. Flammutoxin has three biological activities similar those volvatoxin: (1) direct haemolytic action against human oup O blood cells at a concentration of 25 µg ml<sup>-1</sup>; (2) willy to cause a writhing reaction with a delay before onset a dose of 1.2–2 mg kg<sup>-1</sup> body weight and twenty-two writhg reactions within 10 min of the first writhing reaction;

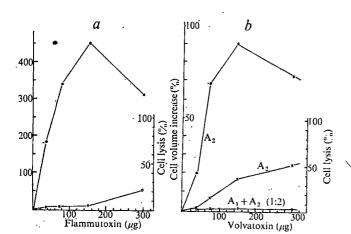

Fig. 2 Effect of a, flammutoxin and b, volvatoxin on the swelling of Ehrlich ascites tumour cells. The tumour cells  $(2 \times 10^8 \text{ ml}^{-1})$  were treated with various concentrations of flammutoxin. The reaction mixture was incubated at  $37^{\circ}$  C for 5 min and it was centrifuged at 2,300g for 30 min at 4° C with a Wintrobe tube<sup>5</sup>.  $\bullet$ , Cell volume;  $\bigcirc$ , cell lysis.

<sup>\*</sup> Measured by alkaline hydrolysis method<sup>6</sup>.

(3) effect on the ECG at a dose of 0.25 mg per kg body weight, causing depression of the ST segment and inversion of the T wave (Fig. 1a).

Flammutoxin also has several activities which were not found in volvatoxin A. First, flammutoxin induces a sharp fall in blood pressure (Fig. 1a). Second, it causes the swelling of Ehrlich ascites tumour cells (Fig. 2a). Third, it inhibits the respiration of Ehrlich ascites tumour cells (Fig. 3).

The probability that flammutoxin, like volvatoxin, might consist of two components was tested by gel filtration<sup>2</sup> and SDS acrylamide gel electrophoresis<sup>3</sup>. Flammutoxin was found to contain only one type of molecule with a molecular weight of 22,000. Table 1 shows its amino acid composition<sup>4</sup> which is similar to that of volvatoxin A2. The molecule is rich in lysine;

its isoelectric point is 4.2. The two components of volvatoxin A, A1 and A2, were tested to see whether either of them separately possessed those properties found in flammutoxin but not in volvatoxin A. Volvatoxin A2 was found to cause a decrease of blood pressure (Fig. 1b), lysis of human group O red blood cells, swelling of tumour cells (Fig. 2b), as well as the inhibition of respiration (Fig. 3) of Ehrlich ascites tumour cells. Volvatoxin A2 alone cannot however elicit the writhing reaction.

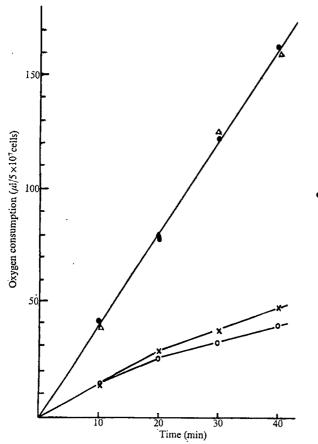

Fig. 3 Effect of flammutoxin on the respiration of Ehrlich ascites tumour cells. One millilitre of Ehrlich ascites tumour cells ( $5\times10^7\,\mathrm{ml^{-1}}$ ) was incubated with flammutoxin and the oxygen consumption was measured by manometric method with a Warburg apparatus (B. Braun Apparatebau, Melsungen, West Germany).  $\bullet$ , Control;  $\times$ , volvatoxin A2 ( $50\,\mu\mathrm{g}\,\mathrm{ml^{-1}}$ );  $\bigcirc$ , flammutoxin ( $20\,\mu\mathrm{g}\,\mathrm{ml^{-1}}$ );  $\triangle$ , volvatoxin A1 ( $20\,\mu\mathrm{g}\,\mathrm{ml^{-1}}$ ) plus volvatoxin A2 ( $50\,\mu\mathrm{g}\,\mathrm{ml^{-1}}$ ).

The activities of volvatoxin A2 were completely abolished by the presence of volvatoxin A1 at weight ratios of volvatoxin A1 to A2 higher than 1:2 (Figs 1a, 2b, 3). Volvatoxin A1 has none of biological activities shown either by volvatoxin A or volvatoxin A2. We tested whether volvatoxin A1 could affect the biological activities of flammutoxin as it affected volvatoxin A2, but we found that it had no effect on flammutoxin.

# Dopamine 3-O-sulphate, an end product of L-dopa metabolism in Parkinson patients

Previous studies from these laboratories¹ have shown that L-3,4-dihydroxyphenylalanine (L-dopa) does not undergo sulphoconjugation in vitro in the cytosol sulphating system of rat tissues whereas dopamine very readily yields a mixture of the 3- and 4-O-sulphates. These observations might therefore serve to explain earlier claims² that sulphoconjugated dopamine constituted a significant proportion of the amine fraction extractable from rat tissues following the administration of \*\*C-labelled L-dopa and raises the question of the role of sulphoconjugation in dopamine metabolism. In man this may be of significance in L-dopa therapy in the treatment of Parkinson's disease since such conjugates might represent either intermediates or end products of metabolism.

The administration of <sup>14</sup>C-labelled L-dopa to normal people is followed by the excretion of sulphoconjugates of dopamine in the urine<sup>3</sup> and Parkinson patients on high oral doses of L-dopa have been shown to excrete up to 80% of the amine in this form <sup>4-8</sup>. It therefore seems that sulphoconjugation plays a significant role in the elimination of dopamine from the system.

In all of these studies, however, no definite proof of the absolute identity of the excretion products has been obtained It has generally been concluded that the 4-O-sulphoconjugate is excreted but in view of our earlier findings that in vitro in ra liver preparations, the 3-O-sulphate is the principal product of sulphoconjugation, such a conclusion might seem incorrect Furthermore we have shown (W.N.J., and F.A.R., unpublished that in the rat the 3-O-sulphate is metabolically inert. It does not undergo desulphation when incubated under a variety of conditions with preparations of the three arylsulphohydrolas enzymes from rat tissues and when administered intra peritoneally or intravenously to rats it is rapidly excreted in the urine unchanged. In these experiments the 4-O-sulphate behaved somewhat similarly although in contrast it underwen appreciable metabolism in vivo before excretion. Attempt have therefore been made to determine the identity of dopamin sulphoconjugates excreted by Parkinson patients on high doses of L-dopa. Urine samples (24 h) were collected from patients attending an out-patients clinic and were stored a -20° C over 2 g of sodium metabisulphite as preservative Before use the thawed urine was filtered through Whatma No. 1 paper to remove any sediment and a 50 ml aliquot of the filtrate was lyophilised after the addition of 20 µg each authentic dopamine 3-O and 4-O-35S-sulphate (prepared described previously<sup>1</sup>, specific activity ≈ 1 µCi mg<sup>-1</sup>) in 2 π of water. The addition of isotopically labelled conjugates aide in locating the relative positions of the excreted metabolite and eventually in determining the completeness of their r covery. The freeze-dried sample was then dissolved in 10 n of water and applied to a column (1.4 $\times$ 35 cm) of Dowex 1 $\times$ ion exchange resin (200-400 mesh, acetate form) which ha been previously well washed with water. The column wa eluted with 0.2 M acetic acid at a flow rate of about 0.5 ml min and 10 ml fractions collected. The eluate was continuous monitored at 280 nm by means of an L.K.B. Uvicord system and radioactivity in the fractions was detected by countir 1 ml of the samples mixed with 10 ml of scintillator (toluen 1 1; Triton X 100, 500 ml; 2,5-diphenyloxazole, 5 g) in Packard Tri-Carb liquid scintillation spectrometer.

The dopamine 3-O-35S-sulphate was eluted between 900 and 1,250 ml and the 4-O-35S-sulphate between 1,300 and 1,700 m

<sup>&</sup>lt;sup>1</sup> Lin, J. Y., Jeng, T. W., Chen, C. C., Shi, G. Y., and Tung, T. C., Nature, 246, 524 (1973).

(as determined in preliminary experiments). Two peaks of ultraviolet absorption which were clearly separated from the main absorbing band and exactly coincident with the two peaks of radioactivity were observed (Fig. 1). The fractions from the column representing each sulphoconjugate were pooled and the radioactivity of each was measured on 1 ml aliquots to determine ■the total recovery of the sulphoconjugates from the column. A portion (100 ml) of each sulphoconjugate fraction was vophilised and a sample (1 ml) of the solution obtained by -dissolving the residue in 4 ml of water was subjected to ■hydrolysis by heating at 100° C with 2 ml of 0.3 M HCl for 40 min. This procedure had been shown in previous experiments ◆o hydrolyse 96.0% of both the 3-O and 4-O-sulphates without destruction of the liberated dopamine which could then be -determined. Portions (2 ml) of the hydrolysates were then -diluted with water to 250 ml for the 3-O-sulphate and to 25 ml for the 4-O-sulphate fractions. This dilution of the fractions was sufficient to make adjustment of their pH unnecessary. The diluted hydrolysates were then analysed for dopamine ■using the trihydroxyindole procedure. The purity of the hydrolysates with respect to dopamine was confirmed by an examination of their excitation and emission spectra. The presence of other catecholamine derivatives could not be

The amount of dopamine sulphoconjugate excreted by these Parkinson patients is comparable with that found by other workers although this was not the main concern of the present study. The results however show that the 3-O-sulphate is certainly the predominant conjugate and is consistently so, even in patient no. 3 where the total amount excreted is rather •ow. It therefore seems that the sulphoconjugation of dopamine n the human follows a pattern similar to that in the rat and an result in the rapid removal of an appreciable amount of

detected. The results were corrected for the amount of 35S-

95%) from the ion-exchange columns and also the efficiency

■abelled sulphoconjugate added at the beginning, the recovery

of the hydrolysis procedure (Table 1).

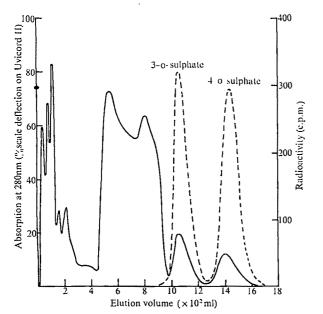

Fig. 1 Elution profile of urinary dopamine sulphoconjugates. Absorption at 280 nm; - - - , radioactivity.

administered dopa from the system. It is also noticeable that the amount of amine sulphoconjugated becomes considerable when dopa is administered orally, emphasising the possible role of the digestive tract in this process. Attention has been drawn to this point in earlier studies on the metabolism of related compounds8. In the mammalian system O-sulphation and O-methylation appear to occur predominantly on the same OH group and they may therefore represent competing processes. The predominant position of O-methylation in various catechols is not only dependent upon the relative nucleophilicities of the phenolic groups but is also strongly influenced by the polarity and orientation of the substituent side chain and other factors. In the case of dopamine, 3-O methylation is favoured near physiological pH. Although less is known about the effect of such factors on the O-sulphation of catechol derivatives, it seems that the situation is somewhat similar (unpublished results). The site of formation of excreted dopamine sulphoconjugates in the system now needs to be established. The identity of the dopamine sulphoconjugate to be found in the tissues<sup>2</sup> and in the blood where it has been claimed to be the only detectable form of the amine<sup>10</sup>, should also be investigated.

The method developed for the identification of the metabolites seems to be generally applicable (W.N.J. and F.A.R., unpublished) and can be of use for the analysis of normal human urine where the excretion pattern is similar although the concentrations are appreciably lower<sup>11</sup>.

We thank Roche Products Ltd for financial support and for arranging access to the patients. W.N.J. is grateful to the SRC for a CAPS studentship.

# Displacement of bound <sup>14</sup>C-fluphenazine by biogenic amines and antipsychotic drugs in homogenates of brain tissue

Considerable evidence suggests that antipsychotic drugs block dopamine receptors at postsynaptic sites in the central nervous system1,2. Receptor sites for neurotransmitter substances, such as acetylcholine<sup>3-5</sup> and glycine<sup>6</sup>, have been studied by measurements of the direct binding of radiolabelled compounds that have high affinity for such sites and cause receptor blockade. In a similar study of biogenic amine receptor sites, I have measured the binding and displacement of the potent phenothiazine antipsychotic drug, fluphenazine, to preparations of brain tissue *in vitro*. I have found that fluphenazine binds to all regions of the rat brain, and that the potency of antipsychotic drugs in displacing fluphenazine correlates well with their clinical efficacy. Dopamine does displace fluphenazine from binding sites, but this is a nonspecific effect shared by other biogenic amines.

<sup>14</sup>C-fluphenazine (4-[3-<sup>14</sup>C-3-(2-trifluoromethyl) phenothiazin-10-yl) propyl]-1-piperazine ethanol, dihydrochloride, 2.4 mCi mol<sup>-1</sup>) was synthesised by F. Dondzila (Chemical Development Department, Squibb Institute) by first reacting 1-chloropropyl-3-<sup>14</sup>C-bromide (3 mCi mmol<sup>-1</sup>, New England Nuclear Corp.) with 2-(trifluoromethyl) phenothiazine to form 10(1-<sup>14</sup>C-3-chlorpropyl)-2-(trifluoromethyl) phenothiazine. This compound was refluxed in the presence of 2-piperazine ethanol to form <sup>14</sup>C-fluphenazine base from which the dihydrochloride salt was obtained. <sup>14</sup>C-fluphenazine dihydrochloride was recrystallised twice from absolute ethanol to yield 98.5% radiochemical purity, which was determined by paper chromatography in two solvent systems, CHCl<sub>3</sub>:ethanol:ammonia, 80:10:1 and CHCl<sub>3</sub>:95% ethanol:ammonia, 10:85:25.

Male Sprague-Dawley rats (180-220 g) were killed by cervical dislocation and decapitated, and their brains were removed immediately. Samples of brain tissue were homogenised in 100 volumes of 0.05 M sodium potassium phosphate buffer (pH 7.4) containing 0.01% Triton X-100 using a Polytron ultraspeed homogeniser. In the standard binding assay, aliquots (10-100 µl) of a striatal homogenate (0.01-0.1 mg protein) were added to 2 ml of phosphate buffer containing 1 µM <sup>14</sup>C-fluphenazine (13,500 c.p.m.) alone or in the presence of 100 mM dopamine or 0.1 mM unlabelled fluphenazine. The mixture, in a 20-ml glass beaker, was incubated at 37° C for 10 min and then poured into a polypropylene centrifuge tube. The beaker was then washed with 1 ml of phosphate buffer. After centrifugation at 40,000g for 10 min, the supernatant fluid was decanted and the pellet was rinsed with 10 ml of phosphate buffer. Bound radioactivity was extracted into 1 ml of ethanol and 10 ml of dioxane-naphthalene liquid scintillation fluid and assayed using a Beckman LS 355 liquid scintillation counter. Counting efficiency for 14C was

Displaceable <sup>14</sup>C-fluphenazine-binding was obtained by subtracting from the total bound radioactivity the amount not displaced by high concentrations of dopamine (100 mM) or fluphenazine (0.1 mM). In a typical assay measuring the binding of <sup>14</sup>C-fluphenazine to a sample of striatal homogenate (0.05 mg protein), 2,400 c.p.m. of <sup>14</sup>C-fluphenazine was bound, of which 70% was displaced in the presence of excess dopamine or unlabelled fluphenazine. The same maximal displacement of bound <sup>14</sup>C-fluphenazine was obtained with excess nonradioactive fluphenazine or dopamine.

Displaceable <sup>14</sup>C-fluphenazine-binding was linear between 0.01 and 0.1 mg of striatal protein (Fig. 1) and was saturable with increasing concentrations of <sup>14</sup>C-fluphenazine. Half-maximal binding of <sup>14</sup>C-fluphenazine to samples of striatal homogenate (0.05 mg protein) occurred at 4.9 µM unlabelled fluphenazine (Fig. 1), as compared with half-maximal displacement by unlabelled fluphenazine, which occurred at 4.6 µM. As half-maximal saturation occurs at nearly the same concentrations of unlabelled and <sup>14</sup>C-fluphenazine, this indicates that <sup>14</sup>C-fluphenazine is biologically equivalent to the nonradioactive drug in terms of tissue binding. The binding of <sup>14</sup>C-fluphenazine in the presence of excess dopamine or nonradioactive fluphenazine was not saturable and increased linearly with increasing <sup>14</sup>C-fluphenazine or tissue concentration.

The optimal pH for displaceable <sup>14</sup>C-fluphenazine binding was 7.4, with a steep decline in binding at more acid and alkaline

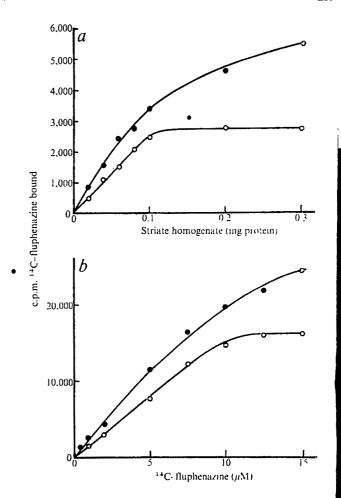

Fig. 1 a, Tissue linearity of displaceable <sup>14</sup>C-fluphenazine binding to components of homogenates of the striate region of rat brain. Dilutions of a 1 in 100 homogenate of striatal tissue incubated with 1 μM <sup>14</sup>C-fluphenazine alone or in the presence of 100 mM dopamine in the standard binding assay. Displaceable <sup>14</sup>C-fluphenazine binding was obtained by subtracting from the total bound radioactivity the radioactivity bound in the presence of dopamine. Each value is the mean of triplicate determinations, with variations of less than 10%. b, Binding of <sup>14</sup>C-fluphenazine to striatal homogenates as a function of the concentration of fluphenazine. The binding of various concentrations of <sup>14</sup>C-fluphenazine alone or in the presence of 1 mM nonradioactive fluphenazine to samples of striatal homogenate (0.05 mg protein) were measured using standard assay procedure. Displaceable <sup>14</sup>C-fluphenazine binding was estimated by subtracting from the total bound radioactivity the radioactivity bound in the presence of excess unlabelled fluphenazine. Each value is the mean of triplicate determinations, which differed from one another by less than 10%. •, Total, (), displaceable.

values. Displaceable binding occurred at incubation temperatures from 4 to 40° C, with a rapid decline at higher temperatures. If, however, striatal homogenates were subjected t 100° C for 10 min, cooled and then incubated with <sup>14</sup>C-flupher azine at 37° C, the displaceable fluphenazine-binding wareduced by only 30%. This suggests that the temperature dependence of the incubation step is a result of the instability of fluphenazine and catecholamines at higher temperature rather than destruction of binding sites. Nondisplaceable <sup>14</sup>C-fluphenazine-binding was not dependent on either pH of temperature. High concentrations (5–100 mM) of Na+, K-Li+, Ca<sup>2+</sup> or Mg<sup>2+</sup> in the incubation medium did not affed displaceable fluphenazine-binding.

The association and dissociation of displaceable <sup>14</sup>C-fluphe azine binding to striatal homogenates as measured by the ra of displacement by 1 mM unlabelled fluphenazine was rapibeing fully equilibrated within less than 2 min. Reliable d terminations of binding at intervals less than 1 min require

Tissues were prepared and subjected to differential centrifugation '\ sample of P<sub>2</sub> pellet was resuspended in 20 volumes of ice-cold listilled water and homogenised with a ground glass homogeniser and centrifuged for 20 min at 9,000g. The supernatant fluid was collected and the pellet, a bilayer with a soft buffy upper coat, was insed with the supernatant fluid to collect the upper layer. The supernatant fluid was then centrifuged at 48,000g for 20 min. The sellets obtained were suspended in 0.5 M sodium potassium phosphate suffer (pH 7.4) containing 0.01% Triton X-100. The data shown represent the mean of four experiments in which the variations among the results were less than 15%. Protein was determined by the nethod of Lowry et al.9 with bovine serum albumin as the reference standard.

nore rapid separation technique, such as filtration, in order
o separate tissue from the incubation media more quickly;
he high degree of binding of <sup>14</sup>C-fluphenazine to various filter
 naterials prevented the use of such a technique.

Endogenous levels of dopamine are highest in the striate egion of the brain, in which most of this amine is localised → dopaminergic nerve terminals<sup>7</sup>; therefore, if displaceable <sup>4</sup>C-fluphenazine binding is specific for dopamine receptors, egional studies of the brain should indicate more binding -o homogenates of the striate region than to other portions of he brain. Moreover, subcellular studies may be expected to -ndicate that the greatest binding to the crude mitochondrial -raction, which contains 'pinched off' nerve endings and the ssociated postsynaptic membrane, in which the neurotransnitter receptor sites are thought to be localised. The crude -aitochondrial fraction prepared from the striate region of he brain exhibts most displaceable 14C-fluphenazine binding, aut other subcellular fractions, in particular the crude microomal pellet, also have extensive binding capacity (Table 1). fter the crude mitochondrial pellet was subjected to hypo-osmo-
